Austrian, associate professor of medicine, Johns Hopkins University School of Medicine, Baltimore, was presented with the gold medal of the Phi Lambda Kappa medical fraternity at its annual convention in Washington, D. C., January 1. The medal is awarded annually to the 'Jewish physician considered as having contributed most to medical science in the preceding year.' The fraternity was founded at the University of Pennsylvania School of Medicine in 1907 and now has thirty-eight undergraduate chapters at universities throughout the country and fourteen alumni clubs.

MASSACHUSETTS

Bill Introduced—H 919 proposes to establish under the state department of health a system of clinics to which persons arrested for intoxication may be committed for treatment.

Personal—Dr. Douglas A. Thom, director, division of mental hygiene, state department of mental diseases, was elected president of the Boston School of Occupational Therapy, December 11, succeeding the late Dr. George M. Kline.

State Society Sponsors Extension Courses—The Massachusetts Medical Society has inaugurated a series of extension courses in twenty-four centers, from Cape Cod to the Berkshires. The faculty giving the courses is composed of staff members of Boston University, Tufts College and Harvard medical schools, and other physicians. A registration fee of \$5 is charged for the series of ten sessions, and the instructors receive no remuneration except the payment of their expenses. Since the state society has adopted this program, the Harvard Medical School has discontinued its extension courses in the Massachusetts area.

Richardson Chair in Obstetrics—The William Lambert Richardson Professorship of Obstetrics has been created at Harvard Medical School under the will of the late Dr. Richardson, former professor of obstetrics and dean of the school. Dr. Richardson's will provides for a gift of \$100,000 to the president and fellows of Harvard College to endow a professorship of obstetrics, and the Harvard Corporation voted to name the chair in his honor. Dr. Richardson also bequeathed \$40,000 to establish the Jeffrey Richardson Fellowship in the medical school, the income to be awarded each year by the faculty of medicine to some deserving medical student who wishes to continue his studies after graduation. Dr. Richardson graduated from Harvard College in 1864 and from Harvard Medical School in 1867. From 1871 to 1907 he served as a member of the teaching staff of the medical school acting as dean from 1893 to 1907. From 1909 to 1915 he was a mem-

ber of the board of overseers. The first incumbent of the new professorship will be named at a meeting of the board of overseers, February 26.

MICHIGAN

Society News—At a meeting of the Calhoun County Medical Society, February 6, Dr. Wilkie Leonard Howard Battle Creek, discussed "Modern Treatment of Tuberculosis." Dr. Jean P. Pratt, Detroit, addressed the Gratiot Isabella Chère Counties Medical Society, December 7, on "Complications of Pregnancy and Labor."

Dr. Fulton to Give Beaumont Lectures—Dr. John Fulton, Sterling professor of physiology, Yale University School of Medicine, New Haven, will deliver the Beaumont lectures, sponsored by the Beaumont Foundation of the Wayne County Medical Society, February 19-20, at the Institute of Arts, Detroit. Three lectures instead of two will comprise the series this year. The subject will be "Studies of the Function of the Cerebral Cortex of Primates."

Tuberculosis Campaign—January 22 marked the opening of a campaign against tuberculosis to be carried on throughout the year, according to *Detroit Medical News*, bulletin of the Wayne County Medical Society. Dr. Henry C. Swann, Chicago, was a speaker in a symposium on tuberculosis given before the society, his subject was "The Pathogenesis of Childhood Tuberculosis." In addition to special programs for physicians, monthly talks for the public and school health lecture feature this year will be an effort to detect early cases by tuberculin testing all contact children and following up systematically the positive reactors.

MISSISSIPPI

Bill Introduced—H 251 proposes to create a board of cosmetic therapy and to regulate the practice of cosmetic therapy.

Personal—Wilbur F. Potter, Ph.D., assistant professor of physiology and pharmacology, University of Georgia Medical Department, Augusta, will direct the course in physiology at the University of Mississippi School of Medicine during the coming year.

Society News—The East Mississippi Medical Society was addressed in Meridian, December 21, by Drs. Edward C. Parker, Gulfport, and William Krauss Meridian, on heart surgery and hematology, respectively. Dr. John W. D. Dick, Natchez, also spoke. At a meeting of the Issaquena Sharkey Warren Counties Medical Society in Vicksburg, December 12, the speakers included Dr. Oscar W. Bethea, New Orleans, on physical diagnosis. Speakers before the Northeast Mississippi Thirteen Counties Medical Society in Tupelo, December 19, were Drs. James W. Lipscomb, Jr., Columbus, postoperative complications and their management, Thomas B. Sellers, New Orleans, neglected gynecologic conditions amenable to office treatment, James P. Ward, Aberdeen, sodium amylal in surgery, and Luther L. McDougal, Booneville, proper care of the insane. The meeting of the South Mississippi Medical Society in Hattiesburg, December 14, was devoted to a discussion of fractures, the speakers were Drs. Joseph W. Stringer, Stringer, Clinton, H. Ramsay, Theophilus E. Ross, Jr., Hattiesburg, and James S. Speed, Memphis, Tenn. At a meeting of the Tri-County Medical Society in Brookhaven, December 12, Drs. Edward C. Parker, Gulfport, spoke on wounds of the heart and John W. Wilson, Monticello, suggestions for improvement of the society.

NEVADA

State Board Reciprocity—The Nevada State Board of Medical Examiners announces that reciprocal relations were established, January 24, with the Alaska Board of Medical Examiners.

NEW JERSEY

Hospital News—A new six-story building with a capacity of 428 beds was recently opened at the Lakeland Sanatorium, Grenloch. This gives the hospital a capacity of about 700 beds.

Society News—Dr. Dan S. Renner, Skillman, among others, addressed the Cumberland County Medical Society at Vineland, in January, on "Sterilization of Mental Defectives." Dr. Lay Martin, Baltimore, addressed the Morris County Medical Society, December 14, at the New Jersey State Hospital, Greystone Park, on "Recent Trends in Investigations of Allergy and Immunity and Their Relation to Medicine." A symposium on peptic ulcer was presented before the Union

County Medical Society, Summit, December 13, by Drs Burrill B Crohn, Albert A Berg and Samuel Goldfarb all of New York.

Bill Introduced—S 73, to amend the osteopathic practice act, proposes (1) to permit persons now holding licenses to practice osteopathy to practice physiotherapy and obstetrics and to administer anesthetics, antiseptics, anodynes, vaccines, antitoxins, germicides, parasitocides, narcotics and antidotes for poisoning, (2) to denominate the practice of osteopathy as the practice of osteopathic medicine and (3) to authorize the examining and licensing of osteopaths to practice surgery. An osteopath desiring to practice surgery must in addition to his osteopathic studies, have served for two years as an intern in a hospital or must have completed a postgraduate course of two years "in a reputable school or college of osteopathy or medicine involving a thorough and intensive study of the subject of surgery."

NEW MEXICO

Meningitis Among Indians—The *Chicago Tribune* January 28, reported that eight Navajo Indians had died on the reservation near the Colorado line of spinal meningitis.

NEW YORK

Bills Introduced—A 364 proposes to prohibit any experimentation or investigation on a living dog. S 297 and A 324 propose to permit any corporation organized under the membership corporations law of the state to establish, maintain and operate, subject to the approval of the superintendent of insurance, a nonprofit plan to provide hospital care to its members. S 336, to amend the law prohibiting the admittance of unvaccinated children to schools in cities of 50,000 or more inhabitants proposes that an unvaccinated child shall be admitted to school on the recommendation of the city board of health or such other board, commission or officers of such city having jurisdiction of the enforcement of this law. A 289 to amend the workmen's compensation act, proposes, in effect, to permit an injured employee to select his own physician and to make the employer liable for his fees. A 316 proposes to create a board of barber examiners and to regulate the practice of barbering. A 296 proposes to accord to hospitals, nurses and physicians caring for or treating a person injured through the negligence of another, liens on all rights of action, claims, judgments or settlements accruing to the injured person or his representative by reason of such injuries. A 325 proposes to create a board of hair dressers and cosmetologists and to regulate the practice of hair dressing and cosmetology. S 304 and A 327 propose that, when an unidentified corpse is found the police shall deliver it to the person having lawful control and management of the nearest public general hospital maintained by the county, who may order the performance of an autopsy unless objection is made by the next of kin within forty-eight hours after death. S 373 proposes to prohibit any hospital supported wholly or partly at public expense from charging any fee for medical, dental or pharmaceutical services rendered while operating a clinic to which the public is invited. S 374 proposes to establish in each public welfare district a central bureau to which persons seeking medical, surgical or other treatment in clinics may apply. This bureau after investigation, is to issue a permit to the applicant entitling him to treatment by a clinic located in the hospital which is nearest the place of his residence. A 410 to amend the workmen's compensation act, proposes in effect to make compensable all occupational diseases arising out of any employment covered by the act. A 415 to amend the pharmacy practice act, proposes, among other things (1) to define a pharmacy as 'any place registered by the board in which drugs, chemicals medicines, prescriptions or poisons are possessed for the purpose of compounding dispensing or retailing or in which drugs chemicals medicines prescriptions or poisons are compounded dispensed or retailed or in which such drugs chemicals medicines prescriptions or poisons are by advertising or otherwise offered for sale at retail,' and (2) to provide that every pharmacy shall be under the personal management of a duly licensed and registered pharmacist. A 417, to amend the pharmacy practice act proposes (1) that a drug shall be deemed to be misbranded within the meaning of the act if its package fails to bear a statement of the percentage contained therein by quantity of barbituric acid and (2) that the act shall not apply to the manufacture and sale of proprietary medicines except those containing poisons deleterious and/or habit forming drugs and chemicals. A 529 proposes to make it unlawful for any person to sell any drug medicine chemical tonic or dental or pharmaceutical preparation including lotions for the care or other treatment of the skin and hair which does not have affixed on the container a label stating the name of the substance and the name and quan-

tity of each ingredient. A 507 proposes to forbid the employment of nurses in any state, county or city hospital or in any hospital supported in whole or in part by public funds for more than eight hours in any one day. A 489 and S 462 propose to accord hospitals treating persons injured through the negligence of other persons, liens on all rights of actions, claims judgments or settlements accruing to the injured persons by reason of their injuries. A 485, to amend the workmen's compensation act, proposes to make compensable dermatitis (venenata) acquired in "any process involving the use of or direct contact with acids, alkalis, acids or oil, or with brick, cement, lime, concrete or mortar capable of causing dermatitis (venenata)." S 450, to amend those provisions of the medical practice act provisions with respect to osteopathy, proposes (1) to denominate osteopaths as osteopathic physicians, and (2) to provide that a license to practice osteopathy shall not entitle the holder thereof to perform any surgical operation involving incision for the opening of a natural body cavity for the removal of cancer or other tumor, for the amputation of an extremity or an appendage, or for the removal of any gland or organ, or part thereof, of the human body, nor shall such license permit the holder thereof to administer drugs except narcotics, anesthetics, antiseptics, vaccines and antitoxins."

New York City

Fifth Harvey Lecture—Dr Everts A Graham, Bryn professor of surgery, Washington University School of Medicine will deliver the fifth lecture of the Harvey Society at the New York Academy of Medicine, February 15. His subject will be 'Clinical Application of Some Recent Knowledge of the Biliary Tract and of the Pancreas.' Edward A Doisy, Ph.D., professor of biologic chemistry St Louis University School of Medicine, delivered the fourth lecture, January 18 on "The Estrogenic Substances."

Personal—Dr Charles H Nammack has been appointed director of the fourth medical division of Bellevue Hospital succeeding Dr Alexander Lambert.—Dr Robert F Loeb associate professor of medicine Columbia University College of Physicians and Surgeons, recently gave a series of lectures at the School of Tropical Medicine, San Juan Puerto Rico on 'Edema and Its Treatment' and 'Dehydration and Shock with Particular Reference to Adrenal Insufficiency.'—Assistants of Dr William Hallock Park, director of laboratories New York City Department of Health, observed his seventieth birthday, December 30 by presenting to him a bronze bas relief plaque of himself. Dr Shirley W Wynne, retiring health commissioner, made the presentation at a ceremony at Willard Parker Hospital.—Dr Karl Landsteiner of the Rockefeller Institute for Medical Research has been awarded a gold medal by the Dutch Red Cross Society for his work on blood groups.—Dr Douglas Quick addressed the First District Dental Society at the New York Academy of Medicine, January 3 on 'Correlation of Clinical, Roentgenological and Pathological Findings in the Diagnosis of Oral Lesions.'—Dr William M Genthner has been appointed assistant professor of hygiene and preventive medicine at Brooklyn Polytechnic Institute.

Society for Prevention of Asphyxial Death—The second annual conference of the Society for Prevention of Asphyxial Death will be held at the Hotel Biltmore, February 19-20. The subject will be approached from three angles: research, instruction and practice. Among the speakers will be Drs Chevalier Jackson, Philadelphia, Harrison S Martland Newark, N J, Royd R Sayers of the U S Public Health Service, Washington, D C, Leon A Fox of the U S Army Medical Corps, Ernest W Brown of the U S Navy, Pol N Coryllos, Charles Norris Henry Hall Forbes, James J Walsh and Horatio B Williams. At an evening session Dr Wendell C Phillips former president of the American Medical Association will discuss asphyxia as a problem of medical education and Col F L Devereux will demonstrate the use of sound pictures as a teaching medium. A dinner will be held the second evening in memory of the late Dr Joseph O Dwyer who has been called a pioneer in this field. There will be scientific and technical exhibits dealing with prevention of asphyxial deaths. Among the exhibitors in the former will be Dr Martland, who will show charts, graphs models, photographs gross and microscopic pathologic specimens, Alexander O Gettler, Ph.D. chief city toxicologist of New York, the chloride test for submersion and chemical determination of carbon monoxide poisoning the American Telephone and Telegraph Company work undertaken by this firm on electrical shock Yale University, New York Post-Graduate Hospital and other medical groups. There will be also an exhibit of approved apparatus used in the treatment and prevention of asphyxia.

OHIO

Annual Banquet—The Mahoning County Medical Society held its annual banquet at the Youngstown Club, Thursday, February 1, with Dr. Morris Fishbein, Chicago, editor of *THE JOURNAL*, as the guest speaker. Dr. Fishbein's subject was "Changes in the Nature of Medical Practice."

Public Health Lecture by Dr. Doull—Another lecture will be added to the series for the public presented by the Cleveland Academy of Medicine March 18, when Dr. James A. Doull, professor of hygiene and public health, Western Reserve University School of Medicine, will speak on "Leprosy in the Past and Present." Dr. Doull has recently returned from a five months visit to the Philippine Islands where he made an epidemiologic study under the auspices of the Leonard Wood Memorial for the eradication of leprosy. His principal project was a census and examination of the inhabitants of a small island Cordova with a population of about 6,000. The incidence of leprosy was found to be about 165 per thousand of population. At the second health lecture January 14 the speaker Dr. William F. Bruner agreed to answer questions from the audience. It was stipulated that the questions must be written must not be requests for diagnosis and must be of general interest. More than 150 were submitted, of which 50 were answered. Dr. Bruner lectured on care of the eyes.

PENNSYLVANIA

University News—Dr. Clayton W. Greene, associate professor of medicine, University of Buffalo School of Medicine, delivered a lecture at the Pittsburgh Academy of Medicine, February 7, under the auspices of the University of Pittsburgh on "Present Conception as to the Physiology of the Adrenals Together with its Application to the Treatment of Addison's Disease."

Philadelphia

Scores Made Ill by Poison on Pastry—A baker and about 200 of his customers became violently ill from eating pies that had been sprinkled with a mixture of rat poison with sugar and corn meal recently in the Port Richmond district of Philadelphia. Investigation by representatives of the state and city health departments disclosed that the baker had purchased a supply of corn meal and flour from a grocery store at a receiver's sale. When the materials bought by the baker were loaded a bag in which poison and sugar had been mixed with corn meal to kill rats was accidentally included. Only one person required hospital treatment. The baker was absolved of blame.

Society News—Dr. Edward H. Hatton, Chicago, addressed the Philadelphia County Medical Society, February 14 on "Current Trends in Oral Focal Infection."—Drs. William P. Healy, New York and Frederick C. Irving, Boston, addressed the Obstetrical Society of Philadelphia February 1 on "Experience with Radiation Therapy in Carcinoma of the Cervix" and Braxton Hicks Version" respectively.—Dr. John T. Murphy, Toledo, Ohio, addressed the Philadelphia Roentgen Ray Society, February 1 on "Bone Tumors."—The Aid Association of the Philadelphia County Medical Society distributed \$7,100 in 1933 to needy physicians and their families.

RHODE ISLAND

Bills Introduced—H. 599 proposes that every non-fireproof building used as a hospital or asylum shall be equipped with a system of automatic sprinklers installed in accordance with the rules and regulations of the National Board of Fire Underwriters or the National Fire Protection Association. H. 597 to amend the pharmacy practice act proposes to authorize the state board of pharmacy to register on or before June 30, as a registered pharmacist, every person then registered as an assistant pharmacist.

SOUTH CAROLINA

Changes in State Medical Board—Dr. Joseph T. Taylor, Adams Run, has resigned from the State Board of Medical Examiners because of his appointment as a member of the Sanitary and Drainage Commission of Charleston County. Dr. Josiah S. Matthews, Denmark, was elected president of the board at a meeting November 13.

Health Projects Under Emergency Program—Dr. James A. Hayne, Columbia, state health officer, has been designated by the U. S. Public Health Service to supervise a program of malaria control and other sanitation projects under the Civil Works Administration. The state has been divided into nine districts and numerous local projects have been approved.

Bills Introduced—H. 1345 proposes to make it unlawful for any person other than a registered pharmacist to sell any drugs, medicine or medicinal chemicals included in the United States Pharmacopoeia or the National Formulary. This proposed law, however, is not to apply to persons selling such preparations more than 3 miles from the corporate limits of the nearest city or town. H. 1344 proposes to prohibit the use of any signs or advertising in connection with any store that would indicate that drugs are sold there unless the store is owned by a licensed pharmacist or unless a licensed pharmacist is employed there. This act, however, is not to apply to any store located at a greater distance than three miles from the limits of a city or town in which there is a licensed pharmacist.

Society News—At the annual meeting and banquet of the Marlboro County Medical Society in Bennettsville, January 12, scientific addresses were presented by Drs. John Shelton Horsley, Richmond, on "Cancer of the Colon and Rectum," Beverly R. Tucker, Richmond, "Lancephalitis," Wilbur C. Davison, Durham, N. C., "Lung Abscess," and Archibald Johnston, Buist, Charleston, "Endocrinology in Its Relationship to the Female Generative Organs." Dr. Robert E. Abell, Chester, president, South Carolina Medical Association, discussed problems of the state society and Dr. Edgar A. Hines, Seneca, secretary, the federal emergency relief program.—Dr. Victor H. Bassett, Savannah, Ga., addressed the Medical History Club of Charleston, January 4, on the early history of the Georgia Medical Society.

VIRGINIA

Bill Introduced—A bill introduced in the House of Delegates by Mr. Witten, and referred to the committee on general laws, proposes to repeal the laws relating to narcotic drugs and to enact the uniform narcotic act. A bill introduced in the House of Delegates by Mr. Hobson, and referred to the committee on asylums and prisons, proposes to provide for the operation of a state sanatorium for inebriates. Apparently any person under 30 years of age who has been intoxicated not less than three times within any period of three months can be committed to this institution for treatment. A bill introduced in the House of Delegates, January 19 by Mr. Moffett, and referred to the committee on asylums and prisons, proposes a procedure whereby persons afflicted with insanity, epilepsy or feeble-mindedness may, on the recommendation of a lunacy commission, consent, through their proper representatives, to eugenic sterilization, the operation to be performed at the expense of the state. If a person brought before a lunacy commission and found to be afflicted with insanity, epilepsy or feeble-mindedness refuses to consent to sterilization, the commission may commit him to a state hospital for the insane where, presumably, his aseualization can be effected by means of the existing sterilization law. A bill introduced in the House of Delegates by Mr. Moss, January 25 and referred to the committee on asylums and prisons, proposes to make it unlawful for any person to fail to pay a bill for hospital care obtained by fraudulent misrepresentation as to ability and intent to pay for it. A bill introduced in the House of Delegates by Mr. Witten, January 25, and referred to the committee on asylums and prisons, proposes that interns for the state hospitals shall be selected by a board composed of the superintendents of the state hospitals and a physician member of the general board of directors for the management of the state hospitals for the insane and a psychiatrist in private practice, the latter two to be appointed by the general board. A bill introduced in the House of Delegates by Mr. Fleet, January 26 and referred to the committee on general laws, proposes to create a state board of cosmetic examiners and to regulate the practice of the cosmetic art.

WASHINGTON

Society News—Dr. Roscoe C. Webb, Minneapolis, addressed the King County Medical Society, Seattle, January 15, on "Emergency Treatment of Fractures of the Upper and Lower Extremities." Drs. Brien T. King and Virgil K. Hancock, addressed the society, February 5, on "Hyperparathyroidism and Treatment of Infections by Irradiated Blood Transfusions," respectively. The King County Medical and Dental societies held their annual joint meeting in Seattle, January 2, when Dr. Erval R. Coffey, state director of health, spoke on "Proposed Changes in the Federal Food and Drug Act," Drs. R. H. Somers and Glenn N. Rotton and Jennie I. Rowntree, Ph.D., "Possibilities of Improving Dental Structures," and Herbert C. Miller, D.D.S., Portland, Ore., "Better Service Through Professional Cooperation."

WISCONSIN

Society News—Dr Carl E. Badgley, Ann Arbor Mich., among others, addressed the Milwaukee Academy of Medicine, December 19, on "The Lumbosacral Joint and Its Relation to Sciatica"—Dr Robert A. Arens, Chicago, addressed the Milwaukee Roentgen Ray Society, January 4, on "Modern Trends in Radiation Therapy"—Dr William S. Middleton, Madison, addressed the Columbia County Medical Society December 12, on oxygen therapy—Dr Burton Clark, Jr. Oshkosh, presented a paper on "Carcinoma of the Colon and Rectum" before the Winnebago County Medical Society, Oshkosh December 15—At a meeting of the Medical Society of Milwaukee County, January 12 speakers were Drs. William F. Wegge, on "The Effects of Barbiturates" Lemuel D. Smith "Spiking Operations for Fractured Hips Under Roentgenographic Control", Albert H. Lahmann Jr., and George S. Kilkenny "Recheck of 4000 Obstetrical Cases at the Milwaukee County Hospital"

GENERAL

Journal Changes Name—The *Medical Journal and Record* a semimonthly publication, has changed its name to the *Medical Record*, beginning with the issue of January 3

Dr. Ira S. Wile New York Autosuggested Dreams as a Factor in Therapy

Dr. George J. Mohr and Phyllis Bartelme Ph.D. Chicago Physical and Mental Growth of Prematurely Born Children

Dr. Milton E. Kirkpatrick Cleveland Juvenile Delinquency in Cleveland and Cuyahoga County During the Depression Period

Dr. Franz Alexander Chicago Evaluation of Statistical and Analytical Methods in Psychiatry and Psychology

Committee to Urge Food Study—Dr. William Weston Columbia, S. C., has been appointed chairman and Drs. Mazyck P. Ravenel, Columbia, Mo., and James E. Knighton Shreveport La., members of a committee to confer with federal authorities concerning a nation-wide study of nutritional values of foods in accordance with a resolution adopted at the annual meeting of the Southern Medical Association. This resolution requested the federal government to cooperate with selected medical colleges in various sections of the United States in making chemical analyses of foods with special reference to the role of nutritional deficiency in disease

Southern Tri-State Meeting—The thirty-sixth annual session of the Tri-State Medical Association of the Carolinas and Virginia will be held in Charlottesville Va. with headquarters at the Monticello Hotel and the University of Virginia Medical School, February 12-14. Special guests will be Drs. William D. Stroud and Gabriel Tucker Philadelphia who will speak on 'Coronary Disease' and 'Bronchoscopic Relief of Obstructive Dyspnea' respectively and Mr. W. H. Nickels, Jr. of the Virginia Industrial Commission. Afternoons will be devoted to clinics conducted by members of the staff of the medical school. Among physicians who will present papers will be

Dr. Linwood D. Keyser Roanoke Va. The Problem of Iodine Fast Hypertension

Dr. James A. Lyon Washington D. C. The Angina Syndrome

Dr. Thomas M. Foley Washington Pathologic Conditions in the Knee Joint

Dr. James W. Gibbon Charlotte N. C. Surgical Lesions of the Large Intestine

Dr. David T. Smith Durham N. C. Fungus Diseases

Changes in Status of Licensure—The New York State Board of Medical Examiners reported the following action

Dr. Maximilian Thomas Raub New York license revoked January 14 on the basis of his having been convicted of a felony embezzlement for which he served a term in the federal prison at Atlanta

The New Jersey State Board of Medical Examiners reports the following action

Dr. Samuel C. Husbands Newark license restored Oct. 14 1933 the license was revoked July 10 1930

The Illinois Board of Registration in Medicine reports the following action

Dr. Joseph P. Moran Chicago license reinstated Oct. 11 1933 pending his continued moral and ethical conduct

The Kansas Board of Registration and Examination reports the following

Dr. Blyford B. Jackson Lawrence license reinstated December 12

The State Medical Board of the Arkansas Medical Society reports the following

Dr. Porter R. Rodgers Searcy license revoked January 10 having been convicted in federal court for possessing counterfeit money. A sentence of three years in the U. S. reformatory imposed Nov. 10 1933 has been suspended until March 1

Medical Bills in Congress—Changes in Status H. R. 7527 making additional appropriations for the continuation of the Civil Works program, has been passed by the House. It provides that the provisions of the Federal Employees Compensation Act shall not apply to Civil Works employees, but that nothing contained in the bill 'shall be construed as precluding the furnishing to such persons at the expense of the United States of such medical, surgical, and hospital treatment as may be necessary to meet the emergency of an injury sustained in the performance of duty' H. R. 7199, making appropriations for the Navy Department, has passed the House. In authorizing an appropriation for increased pay for making aerial flights, the bill provides that none of this appropriation "shall be available for increased pay for making aerial flights by more than eight nonflying officers or observers, to be selected by the Secretary of the Navy." By virtue of this provision officers in the Bureau of Medicine and Surgery in the Navy Department, assigned to aerial flight duty, are discriminated against. **Bills Introduced** S. 2492 introduced by Senator Steiwer (by request), Oregon and H. R. 7217, introduced by Representative Rankin (by request) Mississippi, propose to confer additional benefits on veterans. Among other things, they provide that where a service connection for disability was on March 19 1933, established in accordance with section 200 of the World War Veterans' Act, and such service connection was severed by "An Act to maintain the credit of the United States Government," approved March 20, 1933 or by an act approved June 16 1933, this service connection is to be reestablished. S. 2436, introduced by Senator Duffy, Wisconsin, proposes to authorize the Reconstruction Finance Corporation to make loans to public and private colleges, universities and institutions of higher learning. S. 2455, introduced by Senator Patterson, Missouri, proposes that for the purpose of promotion there shall be credited to the officers of the Medical Corps of the Army all active service as officers of the Medical Reserve Corps rendered by them between April 23, 1908, and April 6, 1917. S. 2490, introduced by Senator McKellar, Tennessee, proposes to authorize the erection of a 300 bed veterans hospital in middle Tennessee. H. R. 6778, introduced by Representative McKeown Oklahoma proposes to confer additional benefits on veterans. Among other things, it provides that any World War veteran who served between April 6 1917, and Nov. 11, 1918 not dishonorably discharged suffering from any disability necessitating hospitalization or domiciliary care who is unable to defray the necessary expenses therefor, is to be furnished such hospitalization or domiciliary care in any Veterans' Administration facility, irrespective of whether the disability was due to service. A statement of the veteran that he is unable to pay for such hospitalization or domiciliary care must be accepted by the Administrator of Veterans Affairs as sufficient evidence of that fact. The following bills, conferring additional benefits on veterans, contain a similar provision. H. R. 7048 introduced by Representative Jeffers Alabama, H. R. 7083, introduced by Representative Ellenbogen, Pennsylvania. H. R. 7084, introduced by Representative Moran, Maine, H. R. 7091, introduced by Representative Chase Minnesota, H. R. 7092, introduced by Representative Hastings Oklahoma. H. R. 7100, introduced by Representative Kelly, Pennsylvania, H. R. 7102 introduced by Representative Rankin, Mississippi. H. R. 7133, introduced by Representative Edmonds, Pennsylvania. H. R. 7140, introduced by Representative McFarlane, Texas. H. R. 7141 introduced by Representative Cartwright Oklahoma. H. R. 7151, introduced by Representative Carter Wyoming. H. R. 7152 introduced by Representative Cochran Pennsylvania. H. R. 7203, introduced by Representative Berlin (by request) Pennsylvania, H. R. 7211, introduced by Representative Hope, Kansas. H. R. 7242 introduced by Representative McClintic, Oklahoma, and H. R. 7363 introduced by Representative Ayres Montana. H. R. 7056 introduced by Representative Moran Maine, provides that members of the Telephone Operating Units Signal Corps American Expeditionary Forces who served in the status of civilian employees of the Signal Corps, United States Army shall be considered as having served in the military service of the United States. H. R. 7059 introduced by Representative Ellzev, Mississippi and H. R. 7089 introduced by Representative Jeffers Alabama propose to provide for the further development

of vocational education in the several states and territories H R 7080, introduced by Representative Guver, Kansas provides for pensions for certain soldiers and sailors of the war with Spain, the Philippine insurrection and the China relief expedition, and to certain widows, minor children and helpless children of such soldiers and sailors H R 7144, introduced by Representative Monaghan Montana and H R 7207, introduced by Representative Swank Oklahoma, propose to provide pensions for the aged H R 7298, introduced by Representative McClintic, Oklahoma, provides that veterans with combat service in the World War shall be presumed to have acquired their disabilities in such service H R 7426 introduced by Representative Sirovich, New York, proposes to regulate interstate traffic in food, drugs, nonalcoholic or nonintoxicating beverages, and cosmetics

Government Services

Review of Veterans' Claims by One Hundred and Twenty-Eight Boards

Special boards of review appointed by President Roosevelt to pass on borderline cases of war veterans' presumptive service disabilities found in a consideration of 51,213 cases that 21,955, or 42.87 per cent, were service connected according to the consolidated report recently made public by General Frank F. Hines, Veterans' Administrator. One hundred and twenty-eight boards met in fifty-five regional areas. The percentage of service connected cases in the several areas varied from 23.43 per cent in the Burlington, Vt., area to 74.68 per cent in the area about Charlotte, N. C. Several reasons were advanced for this variance, including personal appearance by veterans or their representatives and credence given to their statements, effective presentation of cases and the fact that some boards were more liberal in their interpretations than others. In addition, the fact that in some areas a larger percentage of veterans had engaged in combat service than in others and the concentration of tuberculous and neuropsychiatric cases in certain regions where hospitals are located were given as reasons for the variations. Thus an unusually large number of veterans suffering from tuberculosis developed as a result of war service live in Arizona, New Mexico, Colorado and North Carolina, and large numbers of neuropsychiatric cases are centered in New York, Philadelphia, Buffalo, Pittsburgh and Hines, Ill. Each review board consisted of three members appointed from nominations submitted by veterans and citizens' organizations and two from the Veterans' Administration. General Hines emphasized the fact that every veteran whose disability has been denied service connection by the special review boards has the right of appeal to the final Board of Veterans' Appeals recently appointed by the President.

Examinations for Army Medical Service

The War Department announces that examinations for admission to the Medical Department, U. S. Army, will be held as follows: Medical Administrative Corps, March 12-16; Medical Corps, March 19-23; and Veterinary Corps, April 16-20. Thirty-nine appointments as first lieutenant in the Medical Corps will be made during the fiscal year 1935, most of them July 1 and shortly thereafter. Examining boards will be constituted at army posts throughout the United States so as to be near groups of applicants and thus hold travel expenses to a minimum. Final results of the examinations will be known about May 1. There are nine vacancies in the Medical Administrative Corps, all of which will be filled in the grade of second lieutenant as of July 1. Eligibility for this examination is limited to enlisted men of the Medical Department of at least two years' service. Examining boards will be convened at stations where the applicants are now on duty. Applications for both these examinations will be received until March 1 for the Veterinary Corps, in which there are six vacancies, until April 1.

CORRECTION

Available Iron in Therapy—In the editorial on this subject which appeared in *THE JOURNAL* Dec. 30, 1933, page 2123, it was said that ferric glutamate was the product used by Elvehjem. We are informed that the material used was actually ferrous glutamate carefully stabilized in the ferrous state, and that an error was made in typing the label of the product this error being carried through to the original article and from the original article into the editorial.

Discussion of the Danger of the Barbiturates

In a discussion at the Society for the Study of Inebriety on the Medicolegal Aspects of Alcohol and Drug Addiction, Sir William Willcox, toxicologist and medical adviser to the Home Office said that the large group of barbituric acid derivatives occupied a foremost place among the drugs of addiction. The danger to the public was greater than from any other group even including the dangerous drugs controlled by special laws and regulations. The barbituric acid group had a special action of a narcotic nature on the higher brain centers. Their continued use might cause impairment of speech and gait, paralysis of the eye muscles and hallucinations of vision. The risk of death from accidental or purposeful overdose was considerable. He had seen a large number of cases of suicide or attempted suicide among persons who had been taking these drugs for long periods. They took an overdose often because their minds were so confused that they did not care what might happen and hoped for the worst. It was essential that the public should have access to them only by medical prescription, which should be returned by the pharmacist and not repeated except by medical order. Physicians should not prescribe a total quantity of these drugs which, if all were taken might be a fatal dose. So many barbituric acid derivatives were being placed on the market that it was difficult to keep pace with them. Some of them were especially toxic. Among the barbiturates he referred to were veronal, medinal, sororal, dialquidronox, herberal, luminal, phrenodrin, evipan (sodium evipan), numbital, ipral, allonal, veramon, gardenal, ciblagin, somnifane, bertol, amital and picroton.

But certain leading physicians do not place the dangers of the barbituric acid derivatives as high as Sir William Willcox does. A discussion on "The Uses and Dangers of Hypnotic Drugs other than Alkaloids" was recently opened by him at the Royal Society of Medicine in which he gave the same warnings. Sir James Purves-Stewart, a neurologist, described three cases of unexpected toxic effects from ordinary dose. He pointed out that while in full doses the barbituric acid derivatives exercised widespread toxic effects on the brain, from cortex to medulla in smaller and repeated doses they might have a special action on special groups of nerve cells—for example on the cortex or the midbrain or cerebellum, or even the spinal cord. The reason for such differences was varying vulnerability of the centers in question. Dr. R. D. Gillespie, a psychiatrist, strongly contested the views put forward as to the dangers of therapeutic doses of the barbituric acid derivatives. The number of recorded cases of dangerous effects from these doses was small. He did not believe that there was on record a case in which either a single or a repeated dose of therapeutic magnitude had caused death in the absence of complicating factors. There was no foundation for Sir William Willcox's assertion that repeated administration in one or more daily therapeutic doses was dangerous, although of course there were idiosyncrasies, as Purves-Stewart himself pointed out. He denied that the barbiturates predisposed to suicide.

Among 5,147 suicides only 13 were accomplished by the barbiturates. Sir Maurice Craig, a psychiatrist, said that these drugs had been given successfully in thousands of cases and that it was most unscientific to condemn them because of a few unfortunate cases. Sir William Willcox replied that he spoke from sad experience of many cases during his long specializa-

tion in toxicology His opponents failed to realize the dangers, and in support of his contentions he offered access to his notes of cases

Destruction of Locusts by Airplane

An airplane is to be used in Rhodesia to put up poison barrages against locusts as they pass across the country. An apparatus for spraying powder into the air has been sent from England and will be attached to the wings of the airplane. When locusts are reported, the machine will go up in search of them and will attempt to fly along the front of the swarm spraying poison into the air so that they will fly into it. This will be a new experiment in the use of aircraft against destructive insects. An airplane has been used to dust such crops as cotton with insecticides and has helped to rid forests of pests, particularly in Canada. But never before has it been used against migrating insects. It will carry 300 pounds of sodium arsenite. What will happen if the airplane gets among a cloud of locusts is difficult to say. Recently an engine was put out of action by a swallow getting jammed in the air intake. Locusts might do the same. The method will probably be to overtake a swarm at a high altitude, descend to its level and spread a curtain of fine powder before it. The powder is expected to remain suspended for some time and to cause heavy casualties in a long column.

Controversy over the Minimum Food Requirements

The report of the British Medical Association committee on the minimum weekly expenditure on foodstuffs that must be incurred to maintain health (*THE JOURNAL*, Dec 21, 1933, p 2061) has aroused a storm of controversy. The minister of health had previously accepted a memorandum of advice from a committee of eminent dietitians consisting among others, of Sir Gowland Hopkins, president of the Royal Society, Prof Edward Mellanby, FRS, and Prof E P Cathcart, FRS, which arrived at a conclusion different from that of the British Medical Association. The dietitians adopted 3,000 calories and 37 Gm of first class protein as the minimum for a person not engaged in more than moderate physical labor, while the figures of the British Medical Association are 3,400 calories and 50 Gm of protein. On the publication of the British Medical Association report the minister of health dispatched a circular to the local authorities stating that he had referred it to his advisory committee as its conclusions differed in important respects from the principles he had laid down for guidance of these authorities in a previous memorandum. His committee now unanimously reports that it does not desire in any way to modify the advice which it had tendered and which it believes can be safely followed. This has elicited a rejoinder in the *Times* from the medical secretary of the British Medical Association, who points out that its committee attempted to set out a minimum standard for the maintenance of health and working capacity. The figure of 3,400 is for calories as purchased in the shop which would be needed if approximately 3,000 is to reach the body after cooking and other losses. The chairman of the advisory committee Prof Major Greenwood FRS replies that it considered the average requirements of a man who was not, as has been insinuated living at a mere existence level" but who was not required to perform more than moderate physical labor. Is the British Medical Association committee, he asks competent to overrule the judgment of physiologists whose life work has been in the field of nutrition and metabolism? Replying to this the medical secretary quotes two sentences from the memorandum. "The figures chosen as standards are not very generous. no account has been taken of wastage and. Any deficit of first-class protein is probably detrimental for the figure adopted as a standard is not high.

The British Medical Association committee has not criticized the conclusions of the first committee but has taken a slightly different view and has in addition gone into the question of cost. But, as pointed out by the chairman of the first committee, this is not a medical question. It is an economic one with which no medical body has special competence to deal. The result of entering into it has not been happy. The association committee found that 5 shillings and tenpence-halfpenny (about \$1.25) was the cost of the minimum diet per week for a man. The popular press at once came out with the cry that the government was proclaiming that this small sum was the proper relief allowance for feeding a man and that the official experts were recommending still less. The government was charged with flouting the physicians of the British Medical Association on a matter on which depended the lives of 2,000,000 workless persons. What should be a purely scientific question has become a matter for scare head lines in the daily press. The point is overlooked that the determination of a minimum is one thing and compelling people to live on it is another and has never been proposed.

Robert Prosser White

Dr Robert Prosser White, well known for his book "Occupational Affections of the Skin," has died at his residence Southport, at the aged of 78. This book was translated into Russian by order of the soviet government and has been published in America and Europe. Dr White's work as factory surgeon and medical attendant to workers in cotton mills, collieries and other industries in the Wigan area induced him to make a special study of occupational diseases. In 1928 Dr Moritz Oppenheim, professor of dermatology in the University of Vienna, visited England to confer with Dr White as to publishing his work in German. Various honors were conferred on Dr White. He was appointed a member of the permanent committee for the study of industrial diseases constituted by the League of Nations and was elected president of the London Dermatological Society. He was associate editor of the *Journal of Industrial Hygiene*.

The Increased Budget for Public Charities in Paris

The new budget of the Assistance publique a Paris, which includes that of the public hospitals, gave rise to a lively debate at a recent meeting of the municipal council. Mr Mourier, director of the Assistance publique, was accused of receiving in the public hospitals large numbers of well-to-do patients. Mr Mourier replied in defense, that the number of such patients did not exceed 7 per cent of the total admissions, and that, of the others scarcely 1 per cent paid the charges that were assessed against them. He added that nearly all exemptions from charges had been made on the recommendation of members of the municipal council, to favor certain of their political supporters. The budget of the Assistance publique in 1913 amounted to 23,000,000 francs (\$4,439,000, prewar exchange). The appropriation this year, is 300,000,000 francs (\$18,000,000 current exchange) for a total budget of 668,176,131 francs (\$40,000,000). However, several new hospitals and sanatoriums with 300 new beds will be completed this year, which will bring the number of beds up to 42,000. Another criticism of Mr Mourier was the exaggerated length of stay of patients in the hospitals. Furthermore it was emphasized, too many foreigners are admitted to the Paris hospitals who pay no part of the hospital charges. It has been suggested that every country through its consuls, should pay the hospital charges of its indigent nationals and that previous reciprocity agreements be abolished.

The Income Tax of Physicians

Parliament experienced great difficulties in balancing the budget that it has adopted. There is no doubt that the deficit is caused by the excessive expenditures created by the soldiers' pensions and by the new social laws. But the influence of the socialists prevents parliament from taking any action to reduce these expenditures and operates rather in the direction of increasing taxation, since taxes are mostly paid not by their constituents but by the middle and the wealthy classes. Hence new regulations applicable to the liberal professions have been adopted. The physicians and the lawyers awaken suspicion in the minds of treasury officials. It is alleged that physicians fail to make honest declarations of their incomes, since it is more difficult to check up on their incomes than on those of industrialists. Similar charges are made against lawyers. It may be that some physicians and lawyers do act in that manner, but the socialist idea is that all members of these professions are assumed to be defrauders until they have furnished proof of being innocent. Henceforth, all physicians must keep a special register in which are to be entered daily all the amounts that they receive from their clients, and the collector of revenue may demand at any time the privilege of inspecting this register. Furthermore the legislator has decreed that the incomes declared by physicians may not be less than four times the house rent. If this arbitrary evaluation is exaggerated it is the physician's duty to furnish the collector, or his deputy, with proof. The Confederation des Syndicats médicaux français filed a protest based on two facts. It is impossible for the physician to keep an account of the sums paid by his clients without giving their names, and that would be a distinct violation of the legal right of privileged communication. Furthermore the arbitrary fixation of professional income is equal to four times the amount paid for house rent is inapplicable to the physician who is compelled for practical reasons to have a more imposing residence in which to receive his clients than he would have if he were not practicing a profession. The protests however were not heeded, owing to opposition from the socialists.

Paul Richer

The death of Dr. Paul Richer, at the age of 84 is announced. Dr. Richer was a member of the Academy of Medicine and as a sculptor, of the Academy of Fine Arts. He had been an intern of the Hôpital de Paris, and a pupil of Charcot, in his celebrated service in the Hôpital de la Salpêtrière which he never left. His remarkable talent for drawing made him a valuable collaborator for the important periodical *Iconographie de la Salpêtrière*. Richer produced a number of excellent sculptures, which were shown at the fine arts exhibits. He was also professor of anatomy at the School of Fine Arts and published numerous volumes illustrated by many of his own drawings, on the physiologic expression of emotions. He produced also a large number of portrait medallions of contemporary medical celebrities.

A New Center of Cardiology

The old central structure at the Hôpital de Versailles is still magnificent though it dates back to the time of Louis XIV. Among the new buildings that have sprung up is one equipped with all modern technical improvements for cardiology. It is under the direction of Dr. Lutembacher. This new institute will relieve the pressure on the two centers in the congested sections of Paris. It is unquestionable that the number of cases of heart disease is constantly increasing. The mortality from heart disease is but slightly lower than that of cancer (108 as against 119). In 1906, 49,889 deaths from heart disease were recorded in France, in 1930 the number had risen to 62,014. This increase is ascribed to overwork, noise, the greater development of emotional life, rheumatism and syphilis.

An endeavor is therefore being made to detect with greater certainty incipient forms of heart disease when they are still curable, by means of radiography and electrocardiography. To the cardiographic center in Versailles will be added, furthermore, another specialized center for rheumatismal disorders, in which Dr. Lutembacher will develop his method of intravenous injections of sodium salicylate. The hospital has no wards—only rooms with two or four beds and rooms for isolated patients. There are two laboratories for histology and microscopy, a laboratory for photography, and a radiographic department. In addition to a large stationary electrocardiograph, there are several portable electrocardiographs. The new edifice constitutes the most complete cardiologic institute in France.

The Action of Crystalline Insulin

After obtaining considerable quantities of crystalline insulin from an American brand of insulin Professor Burger, director of the Medical University Polyclinic in Bonn, carefully studied its effects on animals and diabetic patients. The insulins on the market contain at least one secondary substance that has a mobilizing effect on the carbohydrates of the liver. The many contradictory statements in the literature concerning the physiologic effects of insulin are due in part to the use of a mixture of substances and not a pure preparation. The crystalline product prepared in Bonn corresponds exactly. Burger pointed out in his address before the *Niederrheinische Gesellschaft für Natur- und Heilkunde*, with the Abel product in crystalline form melting point and composition. In determining its action not only the extent to which the blood sugar is reduced but also the duration of its action are considered. The latter depends on the method of administration. The intravenous method is less effective than other methods. The action on diabetic patients is manifested in two phases. Immediately after the injection the oxygen consumption rises and then returns to normal. During the progress of the hypoglycemic phase there is a second increase of the oxygen consumption which is due chiefly to increased respiratory and heart activity and to a certain muscular unrest. The main point of attack of insulin is the musculature, and hence bodily activity increases the action.

Prognosis of Cancer of the Larynx

Professor von Eicken, director of the Hals-Nasen-Klinik at the University of Berlin, reported before the Berlin Medical Society that the results of radium and roentgen therapy with Coutard's method are fully equal to the surgical results. In cancer of the larynx it must be determined whether only one vocal cord is involved, the whole larynx or the hypopharynx is involved. The prognosis is the most favorable when there is only vocal cord involvement. According to the statistics of Sir St. Clair Thomson laryngectomy effects a cure in 80 per cent of the cases. Of the various radiologic methods the speaker recommended chiefly prolonged irradiation by the Coutard method (which provides for about twenty sittings of irradiation, with one-third to one-half erythema dose to be given at each sitting) and the insertion of radium preparations in the thyroid cartilage. Both methods give good results. The vocal cord is preserved. Through good filtration (particularly of the beta rays) it has proved possible to avoid, to a great extent, the troublesome perichondritis formerly observed if the dosage was inexact. The choice between laryngectomy and irradiation must be determined by the aspects of the case. A combination of the two methods is sometimes effective. In extensive metastatic involvement of the lymph glands, removal of the glands, with the subsequent

use of radium, has proved effective. The least favorable cases are the hypopharynx carcinomas, with their extensive metastases to the lymph glands. In many cases treated by von Eicken, the speech did not appear affected. Several patients were treated for recurrences. Some patients, to be sure, have to use a tube, but even after total extirpation a cure may proceed so far that the speech is gradually restored. Concerning the remote effects nothing can be said, as the method is still too new.

A Test of the Capacity of the Nose to Collect Dust

Dr Gunther Lehmann of the Emperor William Institute for the Physiology of Work has worked out a method to determine what percentage of the inspired dust can be retained by the nose. With this method, dust-laden air is blown into the nose, and the air, while the breath is being held, emerges from the mouth. By means of two komometers, the concentration of the dust is measured before it enters the nose and after it emerges from the mouth. It was found that many noses retain up to 75 per cent of the inspired dust, whereas others allow virtually all the dust to pass out. The concentration of the dust plays a small part; likewise the velocity of the air in motion, and the chemical nature of the dust. The observations made it seem that persons with poor dust fixation capacity of the nose are particularly disposed to pneumoconiosis. Therefore, eighty-nine stone cutters who had worked in stone from ten to thirty years were examined. Of this number fifty-three were healthy, while thirty-six had pneumoconiosis. The dust fixation capacity of the healthy workmen averaged about 52.3 per cent, while the average of the workmen with pneumoconiosis was about 22.3 per cent. Of the forty-six stone cutters with a dust fixation capacity above 40 per cent only two presented pneumoconiosis, while forty-four were exempt. Of the stone cutters with a dust fixation between 29 and 40 per cent, five were ill and five were healthy, while two were showing just the first symptoms of disease. Of the thirty-one stone cutters with a dust fixation capacity under 29 per cent, only two were healthy, while all the others were affected with pneumoconiosis. A good dust fixation capacity of the nose affords therefore almost complete protection against pneumoconiosis, whereas persons with poor dust fixation capacity under corresponding conditions are almost certain to develop pneumoconiosis. Applicants for work as stone cutters should be given this test, and those with poor dust fixation capacity should not be allowed to work where a menace of silicosis exists.

Ernst von Romberg

Prof Ernst von Romberg, director of the first medical clinic at the University of Munich died December 18, after a short illness, aged 68. He was the grandson of the distinguished founder of neurology, and he brought honor to the name. As a pupil of Curschmann in Leipzig as a member of the polyclinic in Marburg as a clinical ordinarius in Tübingen, and finally in Munich he introduced advanced ideas into the study of diseases of the circulation and of tuberculosis. In his early years he became known through his book on *Diseases of the Heart and Blood Vessels*. He was director of the crusade against tuberculosis in Bavaria during the years following the war. Romberg was on the editorial staff of the *Deutsches Arch. für klinische Medizin*, the *Zeitschrift für Tuberkulose*, the *Münchener medizinische Wochenschrift* and other journals. His high conception of his duties as a clinical teacher was revealed three years ago by his *Teaching and Learning of Internal Medicine*. His work as chairman of the *Deutsche Arzneimittelkommission* merits great praise. He was distinguished for his comprehensive knowledge and was universally esteemed for his personal qualities.

Seventieth Birthday of Prof Wilhelm His

Prof Wilhelm His, who served for many years as director of the Medizinische Universitätsklinik, celebrated his seventieth birthday, December 29. His father was the anatomist. His grandfather he was trained under Curschmann. In 1902 he returned to Basel as an ordinarius, in 1906 he was called to Göttingen and in 1907 to Berlin as the successor of Ernst von Leyden. His has devoted himself particularly to diseases of the heart and of metabolism. The term "the bundle of His" perpetuates his name. He has carried on research on diseases of the joints, tuberculosis, goiter, and radium therapy, and has participated in campaigns to eradicate charlatanism. He has always left a deep impression on his pupils through his broad education, his gift of combining in artistic form present-day medicine with its historical past, and by his comprehensive survey of cultural fields.

ITALY

(From Our Regular Correspondent)

Nov 15, 1933

Congress of Medicine Pertaining to Sport

Organized by the Associazione internazionale medico-sportiva the International Congress of Medicine Pertaining to Sport was held at Turin and at Rome, under the chairmanship of Prof Ugo Cassinis. The discussion centered about one topic, "Individual Biometric Standards for University Students." The chief speaker Professor Latarjet, emphasized the difficulty of reconciling the various trends to reduce the international standards to a few anthropometric measurements, and the more scientific trend to collect numerous anthropometric, physiologic and psychologic data. The speakers suggested entrusting the establishment of individual biometric standards to an international committee.

Professor Benedetti described standards prepared by the method of Professor Viola, clinician of Bologna. Viola invented a method for evaluating the nervous impulse and the muscular work in the contraction of muscle. It consists in establishing the relation between the average of certain dynamometric measurements and the average of certain circumference measurements of the limbs. The evaluation is important, since there are sports in which rapidity of the nerve impulse is preponderant and others in which muscular strength is the main thing.

Professor Herlitzka of Turin stated that he was opposed to setting up biometric standards, as they may be either too simple or too complex, and it is desirable to leave ample liberty to every medical advisory board associated with a stadium or gymnasium.

Professor Lafranca emphasized the importance of adopting clinical criteria. Successive examinations during the course of training are important, because often at first the disturbance of function does not manifest itself.

Professor Baglioni of Rome distinguished between international biometric standards of a practical nature and those that might serve as a basis for scientific research. He emphasized the great differences in people and pointed out that methods which are purely morphologic and statistical do not express the biologic reality of person the essentials of which are variation which defies all attempts at mathematical evaluation.

Professor Vallebona of Genoa discussed the importance of radiologic examination and suggested the creation of a radiologic record booklet of the lungs for athletes.

The congress decided to entrust to an international commission the preparation of an individual biometric record booklet.

Many other communications were presented. Professor Donaggio discussed the so-called obstruction phenomenon observed in the urine in various morbid conditions, following physical exertion. The intensity of the phenomenon which is

probably due to colloidal protective substances may constitute a test of fatigue. Professor Cassinis spoke of the marked effect on performance in sports produced by adding to the normal diet supplementary protein chiefly of vegetable origin.

Finally, Professor Gassetto announced the selection of an international committee, which has its headquarters in Bologna.

The Antituberculosis Crusade in Italy

The superior council of the public health service has been studying of late the antituberculosis campaign in Italy. The first problem taken up was the purification of the waste waters of antituberculosis sanatoriums on which a special report of a commission was received. The commission held that in every institution provisions should be made for the destruction or at least the sterilization of contaminated excreta before they are permitted to flow into the cesspool. No special provision is necessary for waste waters that flow into a well constructed municipal cesspool since the heavy dilution of the infective material and its dispersion offer a guarantee of protection. Also when the material can be purified by filtration through soil or transported a distance from habitations into the sea or a large watercourse, no special treatment is needed. Otherwise the purification of waste waters of sanatoriums is indispensable. The biologic methods (septic tanks, oxidation beds, activated muds) used for this purpose are unsatisfactory. They are expensive and have little effect on the vitality of the tubercle bacillus. Much better is the treatment with chlorine. If the dosage and the duration of the chlorination are properly regulated (20 Gm. of chlorine per cubic meter of fluid and two hours of contact) the destruction of the tubercle bacillus may be regarded as certain.

The council considered next the hospitalization of patients with surgical tuberculosis. A medical commission reported that patients with bone and osteo-articular tuberculosis should be removed from ordinary hospitals to more suitable institutions on the seashore or in climatic resorts which have specially trained personnel. There are in Italy thirty-one institutions specially equipped for such service. The commission suggested to the superior council the desirability of promoting the growth of heliotherapeutic stations for ambulant patients.

The council then considered the results secured thus far in antituberculous prophylaxis. There is in each province an adequate number of beds for the admission of tuberculous carriers, and aid is provided for tuberculous mothers and their infants. While this organization is in the initial stages, it has 544 beds, in special departments, for tubercle bacillus carriers, 10,991 beds for the children living with tuberculous persons, and 291 beds for infants of tuberculous mothers.

Finally the council considered the provincial antituberculosis dispensaries. The data examined concerned 361 dispensaries in which in 1932 there were 215,024 patients examined, 59,824 of whom were found to have pulmonary tuberculosis, 122,143 were found to be exempt, and 33,057 presented an uncertain diagnosis. In tuberculosis of the lungs and the pleurae, there was a preponderance of females affected. The tracheobronchial types were most prevalent during the first ten years of life, and the pulmonary types around age 23. The classes most affected were workmen, next came domestics, mendicants and persons admitted to shelters.

Congress of Microbiologists

The Italian chapter of the International Society of Microbiology has chosen the following topics for discussion at the fifth congress, to be held in the spring of 1934: (1) "The Filtrable Viruses in General Pathology," chief speaker, Professor Rivera of Perugia, (2) "New Views on the Biology of Malaria Parasites," chief speaker, Prof. G. Alessandrini of Rome, and (3) "The Bacteriophage," chief speaker, Professor

Orsi of Naples. In addition Professor Rondini of Milan will present a paper on "The Chemical Nature of Antigens and Antibodies."

The Crusade Against Tuberculosis

Special measures have been adopted to prevent the spread of tuberculosis in the seminaries and convents. All young men aspiring to the priesthood will be given a rigorous medical examination. The ecclesiastical authorities are planning to institute clinical record cards for all future priests, on which will be recorded all the important facts that progressive legislation may require. This system will gradually be extended to other religious organizations.

The Ancient Urologists

At a recent meeting of the Budapest Royal Medical Society, Dr. Izid Kesztrner, a urologist, read a paper on the history of urology. The development of urology has occurred through the centuries. For 3000 years circumcision has been a religious, obligatory ceremony with the Egyptians. In a king's tomb opened in 1897, evidence of this operation carved on stone was found. A papyrus written between 400 and 500 years before the Trojan war describes how in cases of inability to evacuate the bladder the urine can be removed. In the Ayur Veda written 2000 years ago there is a description of vesicotomy. A great impetus was given to urology by Hippocrates. About 400 B. C. he described diseases of the urinary organs, laying special stress on the odor, color and precipitates in the urine. He wrote also about catheters made of pliable tubular plants and about the way to evacuate an obstructed bladder. He accurately described the symptoms of ureteral calculi. In the ruins of Pompeii a bronze catheter was found in the house of a physician. It was 26 cm. long and 17 mm. wide, with adequate curvature.

In ancient Rome Aurelius Cornelius Celsus (53 B. C. - 7 A. D.), played an important part in the history of urology. His treatise *De medicina libri octo* considers broadly the infirmities of old age. Hippocrates, Celsus and Galen all displayed special urologic knowledge. Celsus, in the domain of venerology, contributed to the study of condyloma acuminatum and gonorrhea. He wrote a long chapter about kidney diseases and disorders of the male reproductive organs and the operative treatment of hydrocele and varicocele. He dealt with the disturbances of urination, catheterism, renal sand, soft stones, and the treatment of calculi. He wrote a special chapter on female vesical calculi.

In the century following Celsus, the leading part was played by Galen who cleared up several erroneous conceptions in urology. He was an adherent of conservative treatment. He sought the cause of gonorrhea in excessive sexual contacts or in exaggerated abstinence.

The ancient Indo-Babylonian, Assyrian, Syrian and Greek writers mentioned a disease the symptoms of which resembled those of gonorrhea. In Moses' books and in the Talmud there are references to gleet, and particularly to prevention by personal cleanliness. The oldest pertinent records in respect of gonorrhea are in the work of Susruta written in Sanskrit and translated into Latin in the nineteenth century by Dr. Francis Hessler. This reveals that contagious sexual diseases occurred in ancient times.

While Hippocrates did not mention gonorrhea, some diseases mentioned under different names are identical with it. Dioscorides dealt minutely with the treatment of venereal and urologic disturbances. Plinius wrote a treatise on venereal diseases. He applied external and internal remedies and knew the complications of gonorrhea in women. Oribasius who

lived in the time of the emperor Julian acting as court physician, used an indwelling catheter, which he prepared from a goose quill and parchment paper. Such catheters he introduced into the urethra for dilation. Paul Aegina first performed bladder irrigation through a catheter.

The Plight of the Budapest Ambulance Society

For forty seven years the Budapest Ambulance Society has supplied first aid medical service by day and by night fifteen motor cars, forty physicians, twenty-seven medical students and 108 volunteers were always on duty to render aid in cases of accidents and fires. During the first eleven months of 1933 their service was required in 52,000 cases. They never charge a fee except when the sick are transported. The institution is financed by voluntary contributions. This support has dwindled so much that the Ambulance Society may be compelled to reduce the medical staff and to put out of commission at least half of its motor cars. To avert this disaster the council of the city of Budapest applied to the government to nationalize the institution. It is doubtful whether the state will undertake to cover the whole budget. It is rumored that the state intends to pay all salaries, leaving the remainder to be raised by appeal to the public.

Contagious Diseases and Tuberculosis in Childhood

At a recent lecture at the Royal Medical Society, Professor Hainiss said that, in children, tuberculosis has the character of a general infection more than in adults. It depends on the amount of infection, the constitution of the individual, the condition and the age what course tuberculosis will take. If the primary effect is not followed by serious processes the disease will assume importance later only if the slumbering infection is awakened by such intercurrent diseases as smallpox, pertussis and influenza. These diseases endanger the already infected organism, but they may create a favorable soil for a fresh tuberculous infection also. Pertussis causes decided changes in the lungs, as does measles. In influenza, in addition to a specific pathologic agent, various bacterial groups exercise a preponderant influence on the course of the disease. These may dispose the individual in various ways to a flare up of tuberculosis.

After convalescence from one of these contagious diseases it is important to examine children, partly to detect flaring tuberculosis and partly to prevent the possibility of spreading tuberculosis among other children.

Marriages

EDGAR ARMISTEAD BELDEN, Columbia, Mo. to Miss Elinore Scanlon of Philadelphia, at Merdville Pa., January 20.

ROBERT HENRY KAZMIERSKI, Pittsburgh to Miss Carolyn E. Henderson of Oil City, Pa., Nov. 11, 1933.

BERNHARD A. ROGOWSKI, New Haven Conn. to Miss Marjorie Schwarz of New York, Dec. 21, 1933.

HUGH MARTIN HALL, New Carlisle Ind. to Miss Helen Elizabeth Miller of Elkhart, Dec. 26, 1933.

HENRY ARTHUR DUNLAP, Ann Arbor Mich. to Miss Alice Josephine Burkit of Monroe, Dec. 31, 1933.

KEITH W. WOODHOUSE, Van Horn Iowa to Miss Eleanor Chernov of Independence, Dec. 28, 1933.

CARROLL C. LUTTON to Miss Clara Mae McAdams both of Burlington N. C., Dec. 5, 1933.

HAROLD M. CAMP to Miss Doris Holt both of Monmouth Ill., January 28.

JONAS SILVER to Miss Ruth Feigenbaum, both of Brooklyn January 6.

PHILIP B. REED Indianapolis to Miss Genevieve Pickrell January 2.

Deaths

Arthur Lambert Chute ☉ Boston, Harvard University Medical School, Boston, 1895, Chairman of the Section on Genito-Urinary Diseases, 1913-1914, and Member of the House of Delegates of the American Medical Association, 1926-1928, associate professor of urology, Tufts College Medical School, fellow of the American College of Surgeons, member of the New England Surgical Society and American Urological Association, past president of the American Association of Genito-Urinary Surgeons, on the staffs of the Robert Breck Brigham Hospital, St. Elizabeth's Hospital and the Boston Dispensary, the Josiah B. Thomas Hospital, Peabody, Newton (Mass.) Hospital, Leonard Morse Hospital, Natick and the Somerville (Mass.) Hospital, aged 64, died, January 12, of disease of the aortic valve.

Frank Dormer Jennings ☉ Brooklyn, Columbia University College of Physicians and Surgeons, New York 1902, clinical professor of surgery, Long Island College Hospital, past president of the Medical Society of the County of Kings, fellow of the American College of Surgeons, on the staffs of the Mary Immaculate Hospital, Jamaica Lutheran Hospital, Williamsburgh Maternity Hospital, Greenpoint Hospital, St. Catherine's Hospital and St. Cecilia Maternity Hospital and the Menorah Home for the Aged, aged 53, died, January 26, of coronary thrombosis.

George Tryon Harding, Jr. ☉ Columbus, Ohio, University of Michigan Medical School, Ann Arbor, 1900, fellow of the American College of Physicians and member of the American Psychiatric Association, past president of the Columbus Academy of Medicine, formerly clinical lecturer, Ohio State University College of Medicine, neurologist to the Grant Hospital, president and medical director of the Columbus Rural Rest Home, Worthington, aged 55, died, January 18, of cerebral hemorrhage.

Paul Churchill Hutton ☉ Colonel M. C., U. S. Army, Chicago, Columbian University Medical Department, Washington D. C., 1897, veteran of the Spanish-American and World wars, entered the regular army as an assistant surgeon in 1901, in 1906 was promoted to captain in the medical corps and was made a colonel in 1927, fellow of the American College of Surgeons, member of the Colorado State Medical Society, aged 58, died suddenly, January 27, of heart disease.

Leon Franklin Luburg ☉ Philadelphia, University of Pennsylvania School of Medicine, Philadelphia, 1899, formerly instructor in obstetrics at his alma mater for many years, police and fire surgeon, at various times on the staffs of the Philadelphia General Hospital, Howard Hospital, American Stomach Hospital and the Methodist Hospital, aged 57, died, January 18, of cerebral hemorrhage.

Ellis Duncan, Louisville Ky., University of Louisville School of Medicine, 1896, member of the Kentucky State Medical Association, fellow of the American College of Surgeons, served during the Spanish-American and World wars, formerly county coroner, visiting surgeon to St. Mary and Elizabeth and Kentucky Baptist hospitals, aged 59, died, January 6, of cerebral hemorrhage.

William Wallace Eshbach, Allentown, Pa., Jefferson Medical College of Philadelphia, 1892, member of the Medical Society of the State of Pennsylvania, also a pharmacist, past president of the Lehigh County Medical Society, formerly health officer, aged 61, died, January 8, of cerebral hemorrhage and arteriosclerosis.

Abel Benson George, Burlington Iowa, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1900, member of the Iowa State Medical Society, served during the World War, aged 55, died, Dec. 29, 1933, in the Edward Hines (Ill.) Jr. Hospital, of cerebral hemorrhage.

Matthew Lawrence Carr ☉ New York, College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1892, instructor of oto-laryngology at his alma mater, served during the World War, on the staff of the Vanderbilt Clinic, aged 63, died, January 10, of arteriosclerosis.

John J. Gambill, Jr., Blaine, Ky., Atlanta Medical College, 1895, member of the Kentucky State Medical Association, formerly member of the county board of education, aged 59, died, January 10, in the Memorial Hospital, Huntington W. Va., of cerebral hemorrhage.

Hiram Martin Read, Seattle, Rush Medical College, Chicago 1883, past president of the King County Medical Society.

fellow of the American College of Surgeons served during the World War, formerly city health officer aged 73, died, Dec 27, 1933, of cardiovascular disease

Chester Wilmet De Mott, Independence, Kan. Rush Medical College, Chicago, 1901, member of the Kansas Medical Society, served during the World War aged 58, chief of staff at the Mercy Hospital where he died January 1, of a streptococcal infection

Leroy Clarke Hedges, Chicago, Chicago Homoeopathic Medical College, 1890, past president of the Colorado State Medical Society and formerly member of the state board of medical examiners, aged 74, died, January 17 of cerebral hemorrhage

Henry Edward Armstrong & Billings, Mont. Trinity Medical College, Toronto, Ont., Canada 1894 fellow of the American College of Surgeons on the staffs of the Billings Deaconess Hospital and St. Vincent's Hospital aged 66 died January 10

Eugene Abraham Darling & Cambridge, Mass. Harvard University Medical School, Boston, 1894 fellow of the American College of Surgeons, for many years on the staff of the Cambridge Hospital aged 65, died, January 9 of coronary sclerosis

Gudmund J. Gislason & Grand Forks, N. D. Illinois Medical College, Chicago, 1906 fellow of the American College of Surgeons, on the staffs of the Grand Forks Deaconess and St. Michael's hospitals aged 56 died, January 3, of heart disease

Howard Hodson Austin, Springfield, Ohio Eclectic Medical Institute, Cincinnati 1903 member of the Ohio State Medical Association served during the World War for twelve years county coroner, aged 53 died January 16 of heart disease

Floyd Leslie Echols, Perry Point, Md. Medical College of the State of South Carolina Charleston 1924 on the staff of the Veterans Administration Hospital aged 41 died Dec 25 1933 in the Mount Alto Hospital Washington D. C.

John Fraser Barbrick, Pasadena, Calif. American Eclectic Medical College, Cincinnati 1893 Atlanta (Ga.) College of Physicians and Surgeons 1900 California Eclectic Medical College, Los Angeles 1910, aged 65 died Dec 29 1933

Joseph Theodore Woodward, East Moline, Ill. Medical College of Indiana Indianapolis 1894 served during the World War, on the staff of the East Moline State Hospital aged 63 died, Dec 24, 1933, in Peoria, of coronary thrombosis

Bertrand Dean Ridlon, Gorham, Maine Medical School of Maine, Portland, 1894 member of the Maine Medical Association, served during the World War aged 65, died, Dec 9 1933, of coronary thrombosis and myocarditis

George Henry Donahue, Northport, N. Y., College of Physicians and Surgeons, Medical Department of Columbia College, New York 1882 member of the Medical Society of the State of New York, died Dec 31 1933

Larcus B. Allen, Alexander City, Ala. Tulane University of Louisiana Medical Department, New Orleans 1912 member of the Medical Association of the State of Alabama aged 46 died, Nov 18 1933, of Hodgkin's disease

Robert James Barritt & Pawhuska, Okla., Tufts College Medical School Boston, 1921, formerly secretary of the Osage County Medical Society aged 40 died January 10 in the Research Hospital, Kansas City, Mo.

Louis Nagorsky, New York Long Island College Hospital, Brooklyn, 1910, member of the Medical Society of the State of New York, aged 50 died suddenly January 12, of heart disease, at Jersey City, N. J.

John Eldridge Dubell, Columbus, N. J. University of Pennsylvania School of Medicine, Philadelphia 1893, member of the Medical Society of New Jersey aged 60 died Dec 31 1933 of carcinoma of the prostate

James Henry McClure, Cornelia, Ga. University of Tennessee Medical Department, Nashville, 1892 member of the Medical Association of Georgia served during the World War, aged 69, died, Dec 7, 1933

Jay William Dounce, New York Syracuse University College of Medicine, 1900, served during the World War aged 57, died January 12, in the Rockefeller Institute Hospital of bronchopneumonia

James Bernard Fitzgerald, Boston Boston University School of Medicine, 1899, College of Physicians and Surgeons Boston 1902 aged 73 was found dead Dec 23, 1933, of nephritis and heart disease

Howard Herrington, San Francisco, University of Michigan Medical School, Ann Arbor, 1894 formerly on the staff of the Franklin Hospital, aged 67, died, Dec 29, 1933 of cerebral hemorrhage

George Francis Berry, Kansas City, Mo., University of Missouri Medical College of Kansas City 1897 member of the Missouri State Medical Association, aged 66, died, January 4 of pneumonia

Wentworth Darcy Vedder, Pottstown, Pa. College of Physicians and Surgeons Baltimore 1880, member of the Medical Society of the State of Pennsylvania, aged 73, died, Dec 22 1933

Lloyd Anson Faulkner, St. Paul, Bennett College of Eclectic Medicine and Surgery, Chicago, 1885, aged 71, died, Dec 18 1933, in the Ancker Hospital, of carcinoma of the hepatic duct

Alban Frederick Emery, St. John N. B., Canada Bellevue Hospital Medical College, New York 1887 aged 77 on the staff of the St. John General Hospital, where he died, Dec 7 1933

Jean Jacques DuMortier, New Haven, Conn., Yale University School of Medicine, New Haven 1931, on the staff of the New Haven Hospital, aged 29 died, January 19 of septicemia

Robert M. Gubbins, Ceresco, Mich. Western University Faculty of Medicine London Ont. Canada 1892 member of the Michigan State Medical Society, aged 69, died January 12

Louis Harry Gribble, Zelenople, Pa., Rush Medical College, Chicago, 1931 aged 31 died Dec 22 1933 in a hospital at Butler, of injuries received in an automobile accident

Lemuel Judson Hunt, Boston Pulte Medical College, Cincinnati 1873 aged 86 died January 11 in the Massachusetts Memorial Hospital of chronic hypertrophic prostatitis

George P. Morris, De Funiak Springs, Fla. Georgia College of Eclectic Medicine and Surgery, Atlanta 1899 aged 83 died Dec 24, 1933, of chronic interstitial nephritis

Benjamin R. Freeman, Spokane, Wash. Medical College of Ohio, Cincinnati 1873 member of the Washington State Medical Association aged 89, died, Nov 28, 1933

Benjamin Franklin George, San Angelo, Texas Memphis (Tenn.) Hospital Medical College 1904 aged 58 died, Oct 28, 1933 of pulmonary tuberculosis

Ferdinand Edmund Parkinson, Saginaw, Mich. Saginaw Valley Medical College 1901 formerly a druggist aged 67 died January 7 of cerebral hemorrhage

Walker F. Cartwright, Columbia, Ky., University of Louisville School of Medicine, 1878 aged 82 died January 9 in Bradenton Fla. of arteriosclerosis

Richard Connell, Seattle, Kentucky School of Medicine Louisville 1889 aged 77, died, Dec 26 1933 of cerebral hemorrhage and arteriosclerosis

Albert Gansen, Oshkosh, Wis. Kentucky School of Medicine Louisville 1898 aged 79 died, January 5 of cerebral hemorrhage and arteriosclerosis

George Hoffman & Chester, Ill. St. Louis College of Physicians and Surgeons 1896, bank president, aged 62 died January 10 of heart disease

John Frances Hudson, Olathe, Kan. Pulte Medical College, Cincinnati 1885, aged 88, died January 11, of nephritis and myocarditis

Thomas Pleasant Callicott, Rives, Tenn., Vanderbilt University School of Medicine, Nashville, 1880, aged 80, died Dec 21, 1933

Hubert Frank Jermain & Milwaukee Wisconsin College of Physicians and Surgeons, Milwaukee 1901, aged 61, died Dec 22, 1933

H. Page Hough, Linden, N. J., Jefferson Medical College of Philadelphia 1878 aged 77, died suddenly, January 20, of heart disease

Louis Harry Ephraim, Baltimore, Maryland Medical College, Baltimore 1902, aged 74 died, Dec 16, 1933 of chronic myocarditis

Eben Jordan Marston, Bath, Maine Medical School of Maine Portland 1893, aged 63 died Dec 30, 1933, of cerebral hemorrhage

James T. Marlow & Tamarac, Ill. Missouri Medical College St. Louis 1886 aged 74 died January 12 of coronary embolism

Bureau of Investigation

S-M-S LABORATORIES

A Mail-Order Fraud of Helen Schy-Man-Ski and Peter B Schyman, M D

For many years a woman known as Helen Schy-Man-Ski and sometimes calling herself "Mother Helen" has exploited a line of nostrums from Chicago. During the last ten or twelve years she has had associated with her one of her sons, who was graduated by Loyola University School of Medicine in 1919 and licensed to practice medicine in Illinois the same year. The son was registered at Loyola first under the name of Peter B Schymanski and also as Peter Bryant Becker. After graduation Peter B Schymanski had his name changed to Schyman by order of the court. It was not long after getting his diploma that Schyman and Helen Schy-Man-Ski were working together, and at the present time P B Schyman, M D, is medical director of Helen Schy-Man-Ski and Sons. The other son connected with the founder of this piece of quackery is said to be known as Edwin B Becker.

Some of the letterheads used by the Schymanski Schyman Becker concern

That the Schy-Man-Ski business has been a profitable one is indicated by the fact that as long ago as 1924 the real estate section of the Chicago *Tribune* reported that Helen Schy-Man-Ski had purchased a piece of property "for an indicated \$130,000."

The Schy-Man-Ski business is mainly local and is one that is hard to control under our present laws. If our present inadequate National Food and Drugs Act could prevent false and fraudulent claims for "patent medicines" being made in any of the advertising, the Schy-Man-Ski business would be more respectable and less profitable. As it is, the Schy-Man-Skis are shrewd enough to confine their falsehood to the collateral advertising not covered by the present law.

During the past year or two the Schy-Man-Ski concern was careless enough to do some of its business by mail, which did bring them into a position where the public could, at least, be protected to some extent against this particular phase of their business. As a result, the postal authorities looked into the matter and on Dec 7 1933, on the recommendation of the Hon Karl A Crowley Solicitor for the Post Office Department, the Postmaster General issued a fraud order debarring from the mails the S-M-S Laboratories, Inc S-M-S Herb-Nu Health Institute, S-M-S Herb-Nu Remedies, Mother Helen's S M-S Remedies, Mother Helen's S M-S Remedies Company, Mother Helen's S M S Herb Nu Remedies and their officers and agents as such. Unfortunately, the fraud order was not extended to cover the name of Helen Schy-Man-Ski and Sons Helen Schy-Man-Ski herself or Peter B Schyman. It is doubtful also whether the amount of business that this quick concern was doing through the mails was very large in comparison with the total business that it does in this field.

According to the memorandum to the Postmaster General recommending the issuance of a fraud order the S M-S Laboratories is a corporation owned by Dr P B Schyman Mrs Helen Schy Man Ski his mother and Edwin B Becker his brother. Under that name as well as the other names that

have been mentioned, Dr Schyman is engaged with his family in offering to diagnose and furnish herb preparations for the cure of the most serious diseases through the mails. Business is obtained in the way that mail-order quacks usually obtain their business, through advertising in newspapers both foreign language and English language by direct mail circularization, and by radio. Those who answered such advertisements were sent a symptom blank which they were told to fill out and return. The government collected evidence to show that Schyman and his mother and brother claimed the ability to diagnose and cure by herbal medication on the mail order plan such conditions as tuberculosis, syphilis, diabetes, gallstones, "female trouble," kidney trouble and numerous other serious pathologic states. The Schy-Man-Ski outfit was called on to show cause why a fraud order should not be issued against it. On Nov 16 1933 Peter B Schyman and his attorney appeared in Washington and a hearing was held which consumed four days.

Schyman admitted at the hearing that on the basis of the data called for in the symptom blanks which he and his relatives furnished, it was absolutely impossible to arrive at an accurate diagnosis or to prescribe proper treatment. Of course, medical expert testimony offered by the government corroborated these admissions. In part of the follow-up letters sent out by Dr Schyman and used in the operation of the mail-order fraud, Schyman would state that he had been so busy that he had not had time to give the patient personal attention but that he had now made arrangements to have his "doctor associates" take over a large part of his practice, so that he (Schyman) would now be able to give the patient "personal attention." Yet at the hearing Schyman admitted that although he had exercised general supervision over this mail-order quackery, neither he nor any other physician personally formulated the letters recommending various preparations sent to mail-order patients, but that the work was actually done by his advertising manager and girl employees.

Schyman also admitted at the hearing that sales of "S-M-S Herb Nu Tonic," which is the chief nostrum exploited by Helen Schy-Man-Ski and her two sons, constitute approximately 90 percent of the business done by the concern. In addition, there was a so called kidney tonic, a "Body Home Ointment," a "bathing tea," a preparation called "Rematone," a nerve sedative preparation, a kidney and bladder preparation, a liniment, and others. The Solicitor in his recommendation to the Postmaster General stated that the composition of these preparations was on evidence before him, as was also their lack of curative value. The so called Herb-Nu Tonic was a dark-colored liquid with a bitter taste. According to the Schy-Man-Ski concern, this so-called Tonic contained the following ingredients:

Aloes	Valerian	Fennel
Cascara	Butternut	Icicle root
Chionanthus	Black Cohosh	Pareira Brava
Senna	Culvers Rt	Uva Ursi Leaves
Buckthorn	Echinacea	Juniper Berries
Baking Soda	Anise Seed	Couch Grass
Dandelion	Caraway	Blue Cohosh
Calumbo	Cassia Bark	Clycena
Gentian		

This complex and unscientific mixture of twenty-five ingredients runs true to form for crude nostrums prepared especially for the ignorant of foreign birth. Purgatives and diuretics with sufficient unpalatable drugs to confirm the opinion frequently held that a nasty-tasting mixture must possess great therapeutic virtue.

Even Peter B Schyman at the hearing admitted that neither the Herb-Nu Tonic nor any of his so called special preparations either alone or in combination would cure or materially alleviate cancer syphilis tuberculosis, diabetes gastric ulcer, gallstones, or any of the other serious diseases and ailments that they advertise to cure. It was brought out at the hearing too that although Schyman posed in the literature as a great "herbalist," when he was questioned as to the actions and properties of the various drugs contained in his preparations he displayed a lack of accurate knowledge relative thereto. As a result of the hearing and the investigation the Solicitor recommended the issuance of a fraud order and as already stated the mails are now closed to this quackery. Unfortunately the local and cash-and-carry quackery itself still persists.

Correspondence

VALUE OF ORGANIZATION IN CONTROLLING STATE MEDICINE

To the Editor—The past months have seen the development of federal control not only to an unprecedented extent but to an undreamed one. That control has extended into many fields which were considered exempt from government interference—business, production, agriculture have all been brought under the yoke. Wiser men than I, men whose life work has been in the field of political economy, admit that they cannot foresee the far-reaching effects of these new policies or predict how far they may extend, so that I need not hesitate to confess that I am unable to pass judgment on them even if I were so inclined. I am mentioning them here for a very different reason—because I would call attention to the fact that the medical profession has thus far not only escaped hampering, federal restrictions but has in a sense received federal endorsement—a vote of confidence from the government as it were.

In the bulletin issued by the Federal Civil Works Administration entitled "Rules and Regulations No. 5" under the head of Medical Treatment it is specifically provided that: "In locations where neither public nor designated medical facilities exist, or where the number of such facilities is inadequate to furnish the service required, local Civil Works Administrators are authorized to arrange for medical care by reputable private physicians. This does not include the use of osteopaths or chiropractors unless treatment by such practitioners is recommended by the Government or designated private physician. This recognition of the difference between scientific medicine and the left-handed schools of so-called healing is something which we have failed to achieve in our own state, and to me at least it is most gratifying that such recognition should come to the profession from the federal government."

In still another matter, the government has recognized and paid tribute to the medical profession in its handling of the medical phases of its CWA work. While it provides fixed fees to be paid for hospitalization, for laboratory work for roentgen examination, it does not fix a medical fee schedule beyond providing that "the fees charged shall not be in excess of those charged patients in the same income class as the injured person." It is as though the government recognized that the medical profession in its hippocratic code already possessed all needed regulations, that such a code of necessity transcends any lesser regulations such as might be provided by the NRA or CWA or the PWA.

There is, however, nothing permanent, nothing unchangeable, about the present regulations. The profession still faces a very real danger. If tomorrow the government should find that certain physicians are failing to abide by this code, it can provide new regulations, it can take over the entire medical work of the CWA, arrange to have it done by salaried government employees, and so take the first steps toward state medicine. In other words, you and I, the members of the medical profession as a whole, are at the mercy of the individual physician, our fate, whether or not we are to continue as individual members of a great profession, or are to become mere cogs in the machine called state medicine, depends on whether each and every one of us plays the game. Unless we are mere dreamers, we must admit that no large group of humans is 100 per cent perfect, and we must face the fact that there are sure to be those who will seek personal profit at the cost of the group welfare—unless we as an organization control them.

Group control through organized medicine is the answer to our problem. If it is to be every man for himself there can be no question but that we shall soon find state medicine a

reality. Because I believe that state medicine would be a mistake, a tragedy, not only from the standpoint of the individual physician but from the standpoint of the welfare of the nation and the continued advancement of medical science, I want to stress once more the vital need for organization, for strong organization in medicine. Such organization, and only such organization can insure freedom to the individual and to the profession in medicine. Individualism and freedom in scientific pursuits have meant advancement in the past and we must look to them for advancement in the future. Organized medicine must have the support of every thinking physician if we are to continue to advance.

Working as individuals, we can do nothing to stem the tide if it turns toward state medicine. As members of a great national organization, the American Medical Association, we can do much. But we must remember that this national organization is strong only as it has the support of its component state medical societies, and that these state societies are strong or weak as the county medical societies that compose them are strong or weak, loyal or indifferent. Now is the time for each component county society to show its strength and its loyalty, to hold its membership to the spirit of the hippocratic code that we may escape membership in a mere trade union and the code control of the federal government.

OLIVER J. FAY, M.D., Des Moines, Iowa

Queries and Minor Notes

ANSWERS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address, but these will be omitted on request.

BOOKS AS DISEASE CARRIERS

To the Editor—Please state what restrictions should be put on the circulation of books from a public library among patients in a general hospital, especially on the obstetric floor, which is well isolated from the remaining parts of the hospital.

W. I. CAMPBELL, M.D., New Castle Pa.

ANSWER—This question has been answered in previous issues of THE JOURNAL, for example once in the issue of Sept. 12, 1914, page 964 and reference to it was made in THE JOURNAL April 20, 1912, page 1201. It is also mentioned in Hygiene June 1925, page 358. The disinfection of books was the subject of a note in THE JOURNAL May 23, 1931, page 1819. To all these sources the questioner is referred.

The matter of the transmission of infection by fomites, such as books, has been agitating public health officials and heads of hospitals for centuries. Whereas formerly the danger was considered great, later experience seems to prove that it is small.

It has not been shown that library workers are more susceptible to infections than the general population, although they handle books that have come from homes that are infected and books that are really infected, and most of the writers on the subject after explaining the possibility of danger, conclude that ordinary care is usually sufficient to prevent infection.

On the other hand the biologic study of the habits of bacteria make it clear that the element of danger should not be ignored. Smiley of Providence, R. I., proved bacteriologically that hemolytic streptococci and staphylococci will live exposed to room temperature for three weeks, the staphylococci being a little more hardy. He says that "a safe general rule appears to be that books, not grossly contaminated, if left untouched in a warm room for a few months are not capable of transmitting infection." The germs lived longer inside the books than on the covers. A few months is a long time to entertain a potential danger. Diphtheria will live nearly a year in its membrane and many months on a dry surface. Balmann of London made a study of the streptococci of scarlatina and found that streptococci were definitely present on books that had been sprayed with broth cultures of the bacterium eighteen days before and that under experimental conditions they can be recovered during a period of four weeks.

A report from the Hygienic Institute of Belgium showed that pathogenic bacteria can be recovered from paper money during a period of from four to six weeks.

A distinction must be made of the various forms of infection, especially since the biologic cause of many of them, such as smallpox, measles, rubella and chickenpox, is not known. It is believed that these viruses die rapidly when exposed to drying and air, but it is not the same with diseases caused by spore-bearing bacteria, such as tetanus or anthrax. Little knowledge exists of the life tenacity of filtrable viruses, and Calmette's and Kendall's work on morphologic changes in bacteria opens up new avenues of thought.

An inquiry at the Chicago Public Library elicited the statement that the books are fumigated only when it is known that they come from an infected home. Children's hospitals always wash and otherwise disinfect toys used by successive children and destroy those that have been grossly contaminated.

While hospitals have conquered the graver infections and contagions, such as hospital gangrene and erysipelas, and have made most gratifying improvements in the reduction of suppurations in clean wounds and done wonders in the prevention of cross infections such as diphtheria, scarlet fever and measles they are still far from perfect. Milder suppurations that destroy primary union, mild or greater rises of temperature that retard recovery, occasional cross-infections with all kinds of diseases, so called catgut infections, frequent individual cases or even mild epidemics of pyelitis, unexplained late pneumonias in convalescence in adults and children, pemphigus in the new-born, all these and other complications occur with a disturbing frequency in general hospitals. This means that patients are being exposed to avoidable dangers from within. These dangers are increased by visitors, who are allowed to carry in all kinds of infections from the outside, and by books, which are admitted from a circulating library, to come into intimate contact with the patients' hands and mouths and add to the risk.

It is not easy to disinfect a book and formaldehyde seems to be the most successful. The books are hung on strings in an atmosphere strongly impregnated with formaldehyde for at least twelve hours and before being put away, a few drops of solution of formaldehyde should be sprinkled between each two leaves. Patients suffering virulent diseases should be given only pamphlets and clippings, which are later destroyed.

PAINLESS OBSTETRICS

To the Editor—I notice that a number of men throughout the country are using a so-called painless delivery in obstetric practice. I understand that most of these men give the patient some form of analgesic or anesthetic and do a dilation version and rapid delivery. I should like to have your opinion as to the advisability of this and any other information you will give me about it. If published please omit name.

M D, North Carolina

ANSWER—The type of delivery outlined in the query is pernicious and to a degree criminal if it is performed as a routine and without a definite indication other than the alleviation of pain. During the last few years, efforts have been made to shorten labor artificially. De Lee proposed what he called the "prophylactic forceps" operation, by which he meant the application of forceps almost as a routine when the fetal head was on the pelvic floor and visible. This entailed practically no risk to either the mother or the baby but was intended for and should remain a procedure only for those skilled in obstetrics. Potter advocated almost routine version and extraction at the end of the first stage of labor in order to eliminate the pain of the second stage. Unfortunately this operation, even in the hands of specialists in obstetrics, has a definite maternal and fetal mortality and morbidity. Hence it should not be used as a routine but only for strict indications. Since trouble may arise from version and extraction after there is complete dilatation, how great must the risks be when the cervix is manually dilated before the version is performed? All authorities are agreed that forcible dilation of the cervix during labor, regardless of whether it is done manually instrumentally or by means of a colpeurynter, is in reality forcible tearing apart of the cervix. During and following this procedure there is danger not only of extensive lacerations even rupture of the lower uterine segment but also the risk of serious hemorrhage, severe infection in the broad ligaments and dead or injured babies. Dilation of the cervix followed by version and rapid delivery may be painless to the patient while she is anesthetized, but the painlessness and shortening of labor will usually be more than counterbalanced by discomfort and trouble after delivery. An ample array of drugs exists with which to relieve the pains of labor satisfactorily in most cases. Version and extraction even after complete dilatation should

be performed only by a trained obstetrician, because even he may encounter difficulties. The physician with little obstetric experience will pay heavily for his apprenticeship in learning this operation unless he is well instructed and supervised, but if he performs this procedure through an undilated cervix for no valid obstetric reason except to shorten labor or relieve pain, he is inviting disaster to both mother and child and he will be liable to a court action should injury result to mother or child. The maternal and fetal mortality in this country is unduly high and in a large measure is due to meddlesome intervention during labor. Accouchement force is the worst of all unnecessary obstetric operations. No physician should attempt, and no reputable hospital should permit, the routine employment of the type of delivery outlined in the query.

EPILEPSY

To the Editor—There has come under my attention a girl aged 9 years who is evidently suffering from epilepsy. She is very intelligent is carrying on her school work in the home and is making her grades. At birth it seems that she suffered some head injury which the father says the attending physician called some kind of an intracranial hemorrhage. At 3 years she had a spinal puncture the father does not know why. She has convulsions mostly at night and usually between the evening meal and bedtime. The father relates that when the patient has an empty stomach she has no spells and that occasionally, when she is threatened he gives an enema and she escapes severe attacks if not the attacks altogether. A gastro-intestinal series has never been made and I do not know of any diagnosed intestinal condition that might complicate the case. She has had an appendectomy. The father has spent a good deal of time and money on behalf of the patient but there has been no relief. Phenobarbital seems to do better than any drug tried. The little patient suffers from indigestion it is said. She is underweight but otherwise appears normal. This case has not come under my care for treatment but has been presented for general interest only. If there is anything you might suggest as to an examination and a course of care and suggested treatment, I should be glad to pass it along to the father. Please omit name and address.

M D Texas

ANSWER—Epilepsy is a symptom and not a disease. It may be caused by many diseases that can be diagnosed, even though at times it appears without any cause that can be detected with available methods of study—the so-called cryptogenic epilepsy. Hence the importance of detailed examination. Even when no definite cause is demonstrated by such an examination, however, much can often be accomplished, especially in childhood, by regulation of the diet—the amount of fluids, varying degrees of ketogenesis and so on—with or without the administration of drugs such as the bromides and phenobarbital. Treatment should be instituted as early as possible, as there is a tendency, when the condition is allowed to continue unchecked for the development of an epileptic habit. One cannot advise too strongly, therefore, that this child should be studied by a competent neurologist and pediatrician even if it is necessary to have recourse to a clinic.

PURPURA RHEUMATICA

To the Editor—I have a case of purpura rheumatica under my care. A woman, aged 44 has had the symptoms and signs almost continuously for the past sixteen months. She presents a textbook picture of crops of large purpuric lesions over the arms, hands, face and neck accompanied by itching and burning sensations as well as by localized edema. The lesions change in a few days from pink to red and then to a dark purple. Joint manifestations are scattered but are most severe in the knees where swelling and redness are noted with some attacks. The lesions were first seen on the legs and swelling or edema was first noted here but both have disappeared and have not returned for several months. My available literature has recommended symptomatic treatment only, ultraviolet therapy, blood transfusions and splenectomy. I would greatly appreciate advice as to treatment and prognosis. Please omit name.

M D Pennsylvania

ANSWER—Purpura rheumatica follows no typical clinical course. Although the condition has almost always a favorable termination, there is a tendency to repeated attacks. New manifestations or recurrences may continue irregularly for days or weeks. Recurrence after months or years has been observed. The nature of this type of purpura is by no means clear, but it can be stated with certainty that it is not associated with a reduction of blood platelets or change in the intravascular clotting mechanism. The frequent association of purpura of this type with erythema multiforme, urticaria and edema suggests a change in vascular permeability. Various agents have been suggested as the underlying cause of the change in vessel permeability but they cannot be established in each case with any regularity. In some cases infection can be definitely related to the symptoms and in others hypersensitivity to protein in one form or another has been demonstrated. Many cases, however, are without a well defined etiology. It has been suggested

that the condition is due to an acute capillary weakening from some toxic action similar to that of histamine also that the hemorrhagic cutaneous manifestations are a secondary phenomenon and are frequently preceded by erythematous or urticarial skin manifestations. Treatment is difficult to evaluate. In many cases the condition is self limited. In others treatment of the infection when present or desensitization to the offending protein seems to be followed by good results. Symptomatic treatment consisting of 25 cc of a 10 per cent solution of calcium chloride intravenously or calcium lactate in doses of from 2 to 6 Gm a day by mouth has been recommended. This is considered by some to decrease the permeability of the vessels. When urticaria and edema are prominent symptoms epinephrine subcutaneously has been advised. While splenectomy has been suggested and performed in a few cases the variable and mild course of the malady makes such a radical procedure of doubtful value.

IDENTIFICATION OF SPERM AND SEMINAL FLUID IN VAGINA

To the Editor—Would you please give me whatever information you have concerning the length of time semen will remain in the vagina without mechanical interference (as douching) so that it can be recognized on examination from appearance and odor of the material. The case in question will probably be a court case. A girl aged 16 years was brought to me by her parents for examination. They claimed that she had been found at a party just before being brought to me and they wanted to know if she had been assaulted. She denied having been touched by any one that evening or in fact at any time. Examination showed that the hymen was absent and that the vagina contained a whitish material which had the appearance and characteristic odor of seminal fluid. A medium sized speculum was used in making the examination. She did not complain of pain during the examination. The material was all over the cervix and the walls of the vagina and in the vestibule. She finally admitted having had intercourse a number of times but said that the first time was eleven days before. She absolutely denies any later contact. Would it be possible for seminal fluid to remain in the vagina so that it practically coated the cervix and was much in evidence over the walls of the vagina after a period of eleven days? A prompt reply would be appreciated. Kindly omit name. M D

ANSWER—From the appearance and odor alone one is not justified in assuming that a whitish material on the vaginal mucosa and cervix is semen. Microscopic examination of the material will reveal whether the secretion contains spermatozoa; the fresh hanging-drop preparation showing motile or immotile sperms, epithelial cells and crystals. Stained slides may also be used for sperm identity and may be kept for medicolegal evidence.

A chemical test should also be applied to the secretion for the detection of semen. The one commonly used is the Florence test, in which a drop of a solution of potassium iodide in iodine is mixed with a drop of the suspected fluid. If semen is present, brownish-red rhomboid crystals (lecithin) will form. The results of this test are of medicolegal value.

Owing to the vaginal acidity, spermatozoa rapidly disappear from the vagina but may remain motile in the uterus for a week and in the fallopian tubes two weeks. Runge proved that spermatozoa disappear from the vagina within forty-eight hours. A whitish secretion such as is described is not uncommon in women and may be the result of hypersecretion or vaginal mucosal exfoliation. Smears usually reveal merely pavement epithelial cells.

MALARIA PROPHYLAXIS

To the Editor—1 Do you think a drug prophylaxis should be used in CCC camps in areas in the South where malaria is prevalent? 2 What is the best drug to use and the dose for malarial prophylaxis as for example in CCC camps in Georgia and Florida where malaria is prevalent? 3 Atebrin has been highly advertised in this community as a five day treatment for malarial fever. What is your opinion as to its use for the treatment and prophylaxis of malaria? Is it superior to quinine? 4 What is the best opinion as to the use of plasmochin and plasmochin compound as for treatment and prophylaxis of malarial fever and how does it compare with quinine and atebrin? Please omit name and address and use initials. M D

ANSWER—It is impossible to give dogmatic answers to these questions. Most of the drug prophylaxis has been done with quinine. The consensus now is that quinine will not prevent infection but will prevent clinical attacks. Thus particularly in camps where it is necessary to keep up the efficiency of a group of workers, it is possible to reduce clinical malaria to a minimum over a long period. Many of these individuals, however, will have contracted the infection so that later after the drug is discontinued and particularly if their general resistance is lowered, they may relapse. Quinine hydrochloride is

generally given in doses of 0.3 Gm daily or 1 Gm twice a week. Some authorities suggest from 0.5 to 0.65 Gm daily.

There is evidence that plasmochin acts as a prophylactic actually preventing infection, especially in malignant tertian malaria but many feel that the doses necessary for complete protection are too large to be safe. Some assert that 0.03 Gm a day can be taken for several months without untoward symptoms and will materially lessen the case rate especially of malignant tertian malaria. Certainly even small doses are of public health value because even when they do not materially affect the individual's infection they render the gametocytes noninfective to mosquitoes and are of great ultimate advantage to public health. A safe prophylactic dose is said to be about 0.018 Gm.

So far reports concerning atebrin are few. It is said to destroy curatively all plasmodial forms of benign tertian and quartan malaria but only the schizonts of malignant tertian malaria. It is usually given in doses of 0.1 Gm three times a day and in the treatment of malignant tertian malaria 0.01 Gm of plasmochin is added for the crescents. The course of treatment is from five to ten days. The low toxicity and its tendency to remain for a long time in the body must recommend it for use as a prophylactic but satisfactory evidence for such usefulness is not yet available. Among side actions that have been reported for atebrin are transient yellow discoloration of the skin and gastro intestinal disturbances.

In sum quinine is still of most proved value in the treatment of malaria. Plasmochin has been proved to be a wonderful adjunct particularly because of its action on the gametocytes of malignant tertian malaria. Atebrin alone and combined with plasmochin for malignant tertian malaria may be superior to both the preceding but it is too recent a discovery to permit definite conclusions. Provided malaria in the CCC camps in Georgia cannot be controlled by mosquito reduction some type of drug prophylaxis would seem advisable but with any of the drugs it probably will partially control the symptoms without absolute protection against infection. In view of its promise it would seem admissible to try atebrin (combined with plasmochin if much malignant tertian malaria is present). If this does not give satisfactory results the use of quinine (or plasmochin compound) a mixture of plasmochin hydrochloride 0.01 Gm and quinine sulphate 0.125 Gm, if much malignant tertian malaria is present) would probably be the next best chance.

Neither plasmochin nor atebrin has been accepted by the Council on Pharmacy and Chemistry.

THYROID DISTURBANCE DURING PREGNANCY

To the Editor—A woman aged 27 is now in her fourth month of pregnancy. Prior to conception the thyroid gland was scarcely palpable except for a firm nodule measuring 1 by 2 cm in the upper pole of the left lobe of the gland. During the past two months this nodule has approximately doubled in size and the remainder of the gland has become more easily palpable. There are no clinical signs of hyperthyroidism except a slight emotional instability at times and this could be accounted for by worry over economic conditions. A basal metabolic rate has not been determined owing to distance from the city. The adenomatous area is beginning to exert a feeling of pressure but is not sufficient to make the patient aware of it all the time. No physical signs of pressure are demonstrable as yet. Please advise what iodine therapy you would recommend in this case and over how long a period it should be used. Kindly omit name and address. M D Maryland

ANSWER—Stimulation of the thyroid to become larger or functionally hyperactive during pregnancy seems to be a frequent occurrence. These phenomena are believed to be due to the participation of the thyroid in the increased metabolic demand incident to pregnancy and lactation. Frequently pressure symptoms and, rarely, severe hyperthyroidism may be observed. Usually the thyroid manifestations of pregnancy are mild and terminate with the termination of the pregnancy and lactation. Occasionally the pregnancy may be the obvious inciting agency in originating a true hyperthyroidism which does not terminate with the pregnancy.

The principles governing management do not differ in pregnancy from thyroid disturbances occurring under other circumstances save that in pregnancy one may more confidently look forward to a spontaneous remission. Iodine in small doses, such as 5 drops of compound solution of iodine twice a day, may be employed to advantage and should be continued throughout lactation. In case severe manifestations due either to pressure or to hyperthyroidism should develop the principles governing management should be the same as though pregnancy did not exist. Under these conditions surgical intervention at the hands of a well trained surgeon in this field, with the patient under the influence of iodine feeding, should not be withheld because of the presence of pregnancy.

CELLULOID BODY CAST

To the Editor—Will you kindly send me detailed instructions for making a celluloid body cast?
M D Michigan

ANSWER—A celluloid body jacket is made as follows. A plaster-of-paris model is made over a thin stockinet. This model is split and removed and rebanded. It is then placed in a drier until perfectly dry. Before the cast is removed, indelible lines are placed across so that when they are matched up after the model has been removed they will ensure the exactness of the shape of the model so that it will be exactly as on the torso.

When the cast is thoroughly dry, the inside is either powdered with talcum or covered with a thin layer of tincture of green soap. Plaster cream is poured into the model until it is filled and a long iron bar is placed in the middle of the model. It is then allowed to dry with the iron bar protruding from the top and bottom.

The original plaster model is then removed and one has an exact positive of the torso. Over this torso a thin layer of stockinet is placed as the first layer for the celluloid jacket.

The celluloid material is prepared as follows. Celluloid comes in various forms; some use old celluloid collars, others use scraps of film from the moving picture industry, others use pyraline. These materials are dissolved in acetone. Other substances are used, but acetone chiefly. The mixture is stirred until a viscid cream is obtained.

The celluloid is then ready to be applied by means of a thin brush. Layer after layer of stockinet or crinoline is used, between each two layers a coating of celluloid cream is applied and just as it is about to dry another layer of material is applied. Usually from six to eight layers of material are used, and after the last layer has thoroughly dried (preferably in the sun) one or two layers of celluloid cream are applied in order to produce a smooth surface. Some use a layer or two on the inside to produce a smooth surface. In some clinics and brace shops, a layer of duco is applied as the final coat. When all the celluloid and duco have been applied the jacket is trimmed at the top and bottom and under the arms and "finished off" with either leather or chamois. Some line the cast with chamois. Straps and buckles or eyelets are applied and laces used.

BRACHIAL BIRTH PALS—DUCHENNE'S PARALYSIS

To the Editor—Will you kindly outline treatment for Duchenne's paralysis due to injury at childbirth? Kindly omit name.
M D New Jersey

ANSWER—Brachial birth palsy, sometimes called obstetric palsy, is a condition found at birth in which there is loss of use of part or all of an upper extremity. It was described by Schmell in 1768 by Duchenne in 1872 and by Erb in 1874. It is usually referred to as Erb's palsy or Erb-Duchenne palsy.

There are three recognized types: the upper-arm type, called the Duchenne-Erb; the lower-arm type, called the Klumpke; and the whole arm type. The more common type, that of the upper arm, involves the fifth and sixth cervical roots and the suprascapular nerve which produces paralysis of the muscles of the upper arm with the exception of the supinator. The junction of the fifth and sixth cervicals is called Erb's point.

The treatment may be divided into immediate, delayed and late. When a new-born child is found to have brachial palsy, he should be treated immediately by gentle manipulation. The affected arm is placed in abduction and external rotation. A bandage looped round the padded wrist with the ends tied to the head of the crib maintains an excellent position. The improvement that occurs in twenty-four hours in certain cases is miraculous.

The indications in all brachial palsies are to stretch contracted tissues to allow overstretched tissues to contract to increase the power of stretched weakened tissues and to increase the circulation of weakened structures. The methods of meeting these indications are correction of the deformity, application of splints, stimulation of muscles by means of the electric current, muscle education, muscle stretching and massage and operation.

The correct position is 90 degrees of abduction of the shoulder, outward rotation of the humerus and flexion of the elbow to 90 degrees, complete supination of the forearm, dorsiflexion of the wrists and extension of the fingers. The best means of obtaining this position is a brace of the type popularized by Sever. One should alternate between the airplane splint, the plinth splint and no splint at all.

Physical therapy includes neuromuscular reeducation, gentle massage, passive and active movements, game rhythm and noise producing toys which the child attempts to grasp. For

older patients, swimming and "climbing up the door with the fingers" are beneficial exercises. Active movements are the most valuable. Until they are possible, passive movements prevent fibrosis. All major positions should be assumed from four to six times daily.

Taylor advocated that, if improvement is unsatisfactory at the end of three months, exposure of the brachial plexus and suture of the damaged nerve ends be done.

The disadvantage in operating during early infancy lies in the small field and the small size of the nerve which makes the technique of suturing difficult. Sharpe advised the exposure of the plexus at the age of 1 month. He sutures the nerves end to end and sheath to sheath and when the separation is greater than 3 or 4 cm, splices the nerves or bridges the gap with several strands of silk or nerve taken from other parts of the body.

Late treatment includes operative correction of the deformity. The chief operations are those described by Sever, Kleinberg, Lange, Thomas and Tubby.

PHOSPHORUS POISONING AND APLASTIC ANEMIA

To the Editor—I recently had a case of aplastic anemia which seems directly traceable to the inhalation of the fumes generated in the process of arc welding. The patient noticed headaches and exhaustion for a year previous to being obliged to stop work because of a severe bilateral epistaxis; these varied in severity with the amount of time the equipment was used and with the type of welding rod. He also noticed no headaches after the use of a bare steel rod. The progression of symptoms seems to show a definite cause and effect relationship. There were five other nasal hemorrhages. The past history is irrelevant. The patient was examined by a number of men who agreed on the diagnosis of aplastic anemia. Six transfusions were ineffective. The autopsy showed no other pathologic changes. Moderate hyperplasia of the bone marrow and fatty degeneration in all organs constituted the only report. Chemical analysis of tissues was not complete. One maker of welding rods here states that the common substances used for coating is a mixture of asbestos, copper sulphate, arsenic and sodium fluoride. None of these substances were found in analysis of the rods used by the patient. The composition seems to be a trade secret and information from commercial concerns is not available. Can you help me to references on similar cases or suggest what the involved chemistry might be? The general survey of the case fitted chronic phosphorus poisoning more nearly than anything else.
OLIVER C. NICKUM, M.D., Omaha

ANSWER—Any arc welder is likely to have also engaged in some acetylene welding. Acetylene may contain hydrogen phosphide as an impurity. It is possible, but improbable, that the welding or welded materials may have included ferrosilicon. If either of these circumstances can be established, poisoning by hydrogen phosphide becomes a tenable assumption.

In the absence of such substances as phosphorus and arsenic, idiopathic aplastic anemia, wholly unrelated to work as the cause, must be regarded as a possible cause of the disorder and death. More often than otherwise, these rare dyscrasias are attributable to obscure conditions within the body, entirely uninfluenced by work conditions or materials. Inquiry should be made as to exposure to benzene or kindred hydrocarbons. Any extended exposure to such substances might lead to exactly the type of clinical picture described in the query. Fumes arising from arc welding are quite capable of causing headaches, lassitude, marked weakness, inflammation of the upper respiratory tract, severe thirst and similar manifestations, but little justification exists for connecting a fetal aplastic anemia with this trade, based on the limited information furnished in the query.

TREATMENT OF ACNE

To the Editor—I am treating a case of acne pustulosa in which the face, neck, chest and upper half of the back are involved. Have you any suggestions for effective treatment of this case?
JAMES PERRY LEVFESTER, M.D., Green Bay, Wis.

ANSWER—A well ordered, simple life should be prescribed, regular hours, plenty of sleep, exercise in the open air and a simple diet. All greasy foods, rich desserts and fats other than milk and butter should be prohibited. Plenty of vegetables and fruits are desirable. Alcohol, chocolate, cocoa, tea and coffee should be avoided. Care must be taken that all vitamins are supplied. If constipation persists in spite of the fruit and vegetables in the diet, mild laxatives may be prescribed. Anemia, if present, should be treated with adequate dosage of iron.

The patient should be instructed to wash the affected parts with hot water and soap, using for a very greasy skin green soap or, if many comedones are present, hand sapolite. The skin is then dried, washed with alcohol and all pus evacuated.

and comedones expressed. Hot towels are then applied for ten minutes, then a cold water or ice rub the skin dried and a lotion applied. This should be done every evening before retiring. The best lotion is solution of sulphurated lime, N. 1 (Vlemmick's solution), diluted with nine parts of water. If its odor is unbearable, lotion may be composed of zinc sulphate and sulphurated potassa—2 Gm of each in 60 cc of rose water may be used in its place. The strength of the lotion should be increased as the case requires. If the skin becomes uncomfortably dry or scaly the lotion should be discontinued until the normal condition returns.

Cases that do not yield within a month or two to such treatment require retic treatment. Superficial pustular cases showing few comedones can often be controlled with ultraviolet radiation, a mild erythema dose twice a week. When a more severe dose is given, as happens in spite of the greatest care, a longer interval should be allowed for recovery. Other cases should be given one eighth or one fourth doses of roentgen rays over each area, with care to avoid much overlapping. These treatments are given once a week until two full erythema doses (1,200 roentgens) have been given. If not clear they are then treated with ultraviolet rays as mentioned. During treatment with roentgen rays careful watch should be maintained for dryness and wrinkling of the skin particularly about the corners of the mouth. If this is seen the treatment must be discontinued. Strong lotions should not be used with full doses of roentgen rays because their action may mask a roentgen effect, or the combined action produce an irritation that would not occur with either one alone.

While the etiologic importance of the endocrine glands in the causation of acne vulgaris is generally acknowledged not enough is yet known of the modus operandi of their action to make practical the use of gland extracts in treatment.

Mention must be made of the experience of A. H. Hoge (Acne Due to Milk Allergy. *THE JOURNAL*, March 8, 1924, p. 788), who demonstrated in allergy to milk in a case of severe acne vulgaris, and cured it by removing milk from the diet.

The treatment of acne vulgaris must be individualized according to the special problems presented by each case.

MENINGOANGULAR SYMPHIS

To the Editor—A white man aged 55 seen in generalized convulsions four months ago had been noticed by the family to have gradually had increasing nervousness for the past two years and frequent lapses of memory and inability to form words. The deep reflexes were very active but there was no Babinski reflex. The pupils were slightly irregular but reacted to light. The spinal fluid and blood Kline tests were both four plus and the colloidal gold curve was 000123000. Considerable improvement followed a course of eight graduated injections of neoarsphenamine up to 0.6 Gm. and alternate injections of sodium bismuth thioglycollate 0.2 Gm. At this time the patient began to complain of itching so the neoarsphenamine was discontinued. A course of trypanamide was begun with 2 Cm. increasing to 3 Cm. a week alternating with sodium bismuth thioglycollate. After the third injection of trypanamide there was a beginning contraction of the visual fields. At this time the patient was also complaining bitterly of the pain caused by the intramuscular injections of the bismuth compound so all parenteral treatment was discontinued and the patient was given potassium iodide. After eight days he was observed to be considerably more nervous complained of feeling electric shocks and of seeing geometric figures. Treatment was resumed with neoarsphenamine 0.6 Gm. for a week alternating with sodium bismuth thioglycollate 0.2 Gm. and again the general health of the patient is improving. The reflexes remain brisk there is no Romberg nor Babinski sign and the pupils continue to react well to light, but the patient is still unable to repeat complex nonsense phrases. However, I do not feel that the neoarsphenamine is doing the most for the meningoangular element of this syndrome. Is there any thing more besides the use of malaria (which he refused) that may be done? Would it be safe to begin injections of trypanamide again? Would alternate injections of trypanamide and neoarsphenamine be beneficial? Please omit name.

M. D. Wisconsin

ANSWER—From the facts given it seems probable that a diagnosis of meningoangular syphilis is justified, but care should be taken to exclude an intracranial neoplasm of non-syphilitic nature. While trypanamide and inoculation with malaria are indicated in parenchymatous syphilis of the brain or in dementia paralytica, the indications in arterial and meningeal syphilis are rather for spirocheticidal remedies such as the arsphenamines, compounds of bismuth and of mercury, and the iodides. In estimating the results from treatment it must be remembered that irreversible damage to nerve tissue may possibly have been done through the thrombosis of arteries, with consequent softening. These arteries may be of small caliber, with the result that the cerebral damage is of small size. The symptoms may be correspondingly localized but nevertheless persistent. Trypanamide is apparently contraindicated in this case.

EFFECTS OF FALCISIOR DUST AND BAKELITE DUST

To the Editor—Please send me information on the effect of excelsior and bakelite dust on the lungs when inhaled in large amounts also the effect of acid fumes when inhaled in moderate amounts over long periods of time.

I. I. JEFFERS M.D. Chicago

ANSWER—Excelsior dust is essentially harmless, except a mechanical action which largely is limited to the upper respiratory tract. Excelsior made from pine and other conifers may be more irritating owing to a content of resin and oxidized products of resin. Bakelite dust is more irritating, owing to the presence of oxidized derivatives of phenol and formic acid. The well known irritating action of bakelite dust on the skin, due to substances akin to hexamethylenetetramine may be duplicated on the membranes of the respiratory tract. Neither excelsior nor bakelite is known to produce any severe condition comparable to the action of silica or asbestos dust. So great a variety of acids exist and so great a diversity of toxic action is known to be caused by them that it is not practical here to furnish any detailed statements. Although hydrocyanic acid and phenol are both toxic little similarity exists in the manner or type of injury produced.

Since not even a list of toxic acids may here be listed, because of space limitations the suggestion is made that information of this character be sought in Henderson and Hagerd's 'Noxious Gases,' published in 1927 by the Chemical Catalog Company.

IRRITATION FROM ENAMELS

To the Editor—I have a patient who acquired eczema about the face and scrotum shortly after painting with green Water Spar-Quick Drying Enamel made by the Pittsburgh Glass Company. The reason a causal relationship is attributed to exposure to this enamel is that he has had eczema on only one previous occasion and that was immediately after using the same type of four hour drying enamel. The prodromal symptoms that followed immediately after using this paint the last time were itching eyes and sore throat. The skin rash then followed. What ingredients in this special paint could cause this reaction? Please omit name.

M. D. Connecticut

ANSWER—Without particular reference to the product of the Pittsburgh Plate Glass Company, it may be stated that various alcohols, acetates and hydrocarbons that enter into enamels and varnishes are skin irritants.

The sore throat and irritated eyes are common manifestations. The hands, forearms, neck and face are the sites commonly involved by dermatitis. Involvement of the scrotum is unusual. Apparently it is possible for painters to become sensitized to some of these agents with the result that trivial exposure is followed by a dermatitis.

Patch tests should be applied to the forearm of the painter using some of the specific product for test purposes, with controls consisting of one or two other enamels and a blank. If the reaction definitely is more from the specific paint than from others in its class it may be concluded that some particular ingredient found only in the specified product is responsible.

If reactions to several enamels are similar, it necessarily must be concluded that the painter is susceptible to the action of various types of enamels.

Further, it will be possible to make patch tests with the various individual ingredients of enamels including such items as ethyl alcohol, amyl and butyl acetates, amyl and butyl alcohols, possibly naphtha, turpentine and benzene. It is possible that the pigment contains chromium, which in itself may be the offending agent.

VASECTOMY—VAS LIGATION FOR STERILITY

To the Editor—Will you please advise me on contraceptive methods? Patients are demanding this information and I would like to be informed of the best method to date. I have two married men that wish to be sterilized. Does tying the cord interfere with sex life? Is there any tendency to atrophy of the testicle or impotence later? Could the vas be reanastomosed later if the patient so desired? I desire medical information on this operation on the male. I am familiar with the textbook operations for tying the cord. R. R. McCrumb M.D. Lansing Mich.

ANSWER—For a complete review of contraceptive methods and details of technique the subscriber is referred to Dickinson and Bryant's book, *Control of Conception*, Baltimore, Williams & Wilkins, 1931. In the same volume, chapter VIII deals with the legal aspect of sterilization. Vasectomy or vas ligation does not interfere with sex life and there is no evidence that it causes atrophy of the testicle or impotence. In fact the Steinach operation of rejuvenation is dependent on ligation of the vas. Reanastomosis is a possibility, but the expectancy of success would be small.

Book Notices

Sex Habits A Vital Factor in Well Being By A Buschke M D and F Jacobsohn M D Translated from the German by Fden and Cedar Paul Foreword by Gerard L Moench M D Cloth Price \$2 50 Pp 204 with 30 Illustrations New York Emerson Books Inc [n d]

This is one of the many books recently published on matters of sex that is really worth reading It was written by two German urologists who have had extensive experience not only in their specialty but also in matters pertaining to the sex life of both men and women In the first part of the book the lay reader is made familiar with the anatomy and physiology of the reproductive organs There is a chapter on puberty in which the anatomic and psychic changes are described for both boys and girls and this chapter should be carefully studied by all parents The authors discuss in detail the sexual impulses in men and women, the lack of these impulses in both sexes, and the abnormalities that may occur There are also chapters on sterility, venereal infections prophylaxis, heredity, eugenics advice concerning marriage and monogamy The authors defend certain extramarital sexual relationships but maintain that the ideal marriage is the one that is truly monogamous The translation is excellent and well printed, and the illustrations are praiseworthy The language employed is plain spoken and perhaps may shock a few people However, most individuals will profit immensely by reading every word in this book, because it is based on a thorough understanding of the sex life of both men and women

Mediaeval and Modern University Ideas and Students Life An Address Before the Medical Students Society of McGill University Montreal October 17 1932 By Horst Oertel Paper Pp 31 Montreal Southam Press Montreal Ltd [n d]

This address was occasioned by the author's selection as honorary president of the Medical Students Society and was published at the request of many students so that it might be enjoyed by a wider circle of readers The author gives an account of the origin meaning and significance of the university movement as a whole with random notes on the ideas and purposes of its masters and students 'Scholars and clerics who studied and taught Aristotle during the day roamed through the woods and hunted the wild boar and wolves at night who would not hesitate to draw the sword to defend their ideas and rights Everywhere an uncontaminated naive strength and sincerity of efforts in spite of lack of conventional manners' Oertel thereupon contrasts the mediaeval with the twentieth century universities regarding the latter as dry technical high schools, for the training of most uninterest-

ing conventional 'good citizens' who conform to the world instead of leading it," ending with a plea to a return to much that has been lost and with the hope that as in the past ages the future university graduate will leave his school with an understanding of everything that makes and enters into human life, which builds and moves the human character. To all of which every academic man will heartily agree. A reader may feel that this distinguished pathologist spoke of anything, a little slightly, or perhaps not enough on the great significance of the modern output of research by universities and was perhaps leaning more to the view that in advance in knowledge (also a function of a university) should come perhaps more from thought, reasoning and intuition than from tedious research in the laboratory. Every cultured person will enjoy reading this interesting address.

Manual of Urology. By R. M. McComie, M.D., F.A.C.S., Professor of Urology, Georgetown University Medical Department. Cloth. Price \$1. Pp. 317 with 46 illustrations. Baltimore: William Wood & Company, 1933.

This small volume covers completely the field of genitourinary diseases. It is brief and for the most part accurate. Isolated sentences may arouse objection. On page 173, relative to therapy of malignant bladder tumors. Radical cure by bilateral transplantation of the ureters and total cystectomy [typographic error—cystectomy is meant] is a surgical curiosity and not a practical procedure. On page 261 regarding non-descent of the testes. Reposition often fails and atrophy following operation is frequent. In view of this and the increased incidence of neoplasm removal should be given careful consideration in unilateral cases and in adults. However, with a few exceptions the volume is readable and especially well adapted for students.

Radiologische Praktika. Herausgegeben von Prof. Dr. W. Alvens. Prof. Dr. Fr. Dessauer und anderen. Band XX. Die Curie Röntgentherapie bösartiger Frauenleiden. Von Dr. Stefan Simon. Leiter der Strahlenabteilung der I. Universitäts-Frauenklinik in Wien. Cloth. Price 12.50 marks. Pp. 122 with 78 illustrations. Leipzig: Georg Thieme, 1933.

The author introduces his monograph with a historical survey of the development of combined radium and roentgen therapy. The indications, contraindications and complications of radiotherapy are discussed briefly and the importance of a complete physical examination before therapy is begun is properly stressed. The general principles of dosage are reviewed. There are excellent descriptions of the physical properties of radium and x-rays and the biologic effects of these agents on normal and pathologic tissues. The various patterns of radiation treatment as to time and intervals of treatments as utilized by various schools are presented. There are detailed descriptions of the effects of radiation on the blood, skin, bladder and intestine. The second part of the monograph deals with the treatment of carcinoma of the vulva, vagina, cervix, uterus and ovaries. Carcinoma of the vulva is treated by the author by a special surface radium applicator. The lymph node areas are treated with x-rays. Of fourteen patients treated by radical irradiation, five are well after a lapse of from one to three years. Different technical methods of irradiating carcinoma of the vagina are described and illustrated. Statistics of various authors vary from 10 to 30 per cent of cures. The author reports thirty cases of vaginal carcinoma treated by radiation, with freedom from disease in six after from one to five years. The author presents his technic for the treatment of carcinoma of the cervix and describes several other accepted methods. Indications, contraindications, complications and results are discussed. Attention is called to the advantages of surgery over irradiation in the treatment of strictly operable carcinoma of the body of the uterus. The author applies 50 mg. of radium for from fifty to sixty hours in two or three sittings and follows this with roentgen therapy. Radical operative removal followed by radiotherapy is advised for operable carcinoma of the ovary. Statistics showing end-results are quoted. This monograph on x-rays and radium in the treatment of neoplasms of the female genitalia is excellent in every respect. It presents concisely, clearly and authoritatively the practical phases of the problem and thereby constitutes a valuable addition to the literature on radiation. It should prove especially useful to the general practitioner and the beginner in the study of radiation therapy.

The Pregnant Woman. By Porter Brown, M.D. Cloth. Price \$2. 1p. 174 with 22 illustrations. New York: Eugenics Publishing Co. Inc., 1933.

The author states that the memory of his mother and the things she told him about her experiences in the bearing of ten children planted in him a desire to help women in the field of motherhood. Unfortunately in his effort to be altruistic the author includes enough information in his book to frighten a large number of women. In the first place he makes the assertions: We see annually the ghosts of thirty thousand dead women many times that number doomed to preventable invalidism for the rest of their lives all of which unfortunate terminations are associated with the functions of reproduction and childbearing. This is a number three times greater than that of the Netherlands and greater than that of twelve other civilized nations.

The present generation of the world has lost more lives from preventable causes in the performance of the function of reproduction than were lost from all causes produced by the World War. I challenge my country to correct this disgraceful condition. These statements which are among the first to be seen by the prospective mother, are sufficient to arouse an undue alarm about childbirth in most young women. Furthermore the author's estimate of 50,000 deaths annually from obstetric causes is entirely too high. Like we he errs in his contention that we should bow our heads in shame because our maternal mortality is disgracefully higher than it is in nearly all other civilized countries in the world. Until a reliable method has been developed of comparing international mortality statistics, it is only fair to ask overenthusiastic obstetric authorities and others to withhold such damaging remarks. The book contains entirely too much about abnormalities during pregnancy and labor which do not properly belong in a book for expectant parents. The author also gives in detail every step of a normal delivery including the enema shaving, the use of sedatives and description of the first stage of labor how the physician and his assistants should scrub the patient and himself and details of the second stage including uterine contractions molding of the head bulging of the perineum and flexion of the head. The book is well written and reveals the extensive experience of the author. There are interesting chapters on superstitions preparation for marriage birth control and abortion, anatomy and physiology prenatal care and care of the mother and new born infant. If a second edition is to be printed it is advisable to eliminate a good deal of the unnecessarily disturbing details of trouble that may befall a pregnant woman.

Les troubles de l'élimination urinaire de l'eau. Étude physiopathologique et clinique. Par Jules Cottet. 14 pages. Price 32 francs. 1p. 21. Paris: Masson & Co. 1933.

The author reviews the older opinions on the various tests of excretion of water by the kidney pointing out that he and Voquez first studied this renal function in 1912. He prefers to have the patient under observation several days during which time he studies various factors including the amount of urine secreted during the day and the night as well as after the ingestion of a large quantity of water. He repeats the observation that the specific gravity of the urine tends to be at a fixed level in the presence of renal insufficiency. In his description of the water exchange in the body, he omits mention of recent observations on water metabolism. He feels that flushing the kidney is important in the treatment of early renal insufficiency and he believes the treatment at Evian is especially beneficial for this reason.

Senile Cataract. Methods of Operating. By W. A. Fisher, M.D., F.A.C.S., Professor of Ophthalmology, Chicago Eye, Ear, Nose and Throat College. With the collaboration of Prof. F. Fuchs, Prof. J. Barraquer, Dr. H. F. Holland, Dr. John Westley Wright, Dr. A. Van Lint and Dr. O. B. Nugent. Second edition. Cloth. Price \$1. 1p. 271 with 183 illustrations. Chicago: Chicago Eye, Ear, Nose & Throat College, 1933.

This edition appearing about ten years after the first, contains the surgeon's own descriptions and illustrations of the technic of operations done by Fuchs, Barraquer, Holland, Wright, Van Lint and the author. The chapter by Professor Fuchs is unchanged since the first edition and Professor Barraquer's shows little change. The chapters by Wright and Holland are newly revised though the former has not changed his technic. Colonel Smith's chapter has been omitted, but

Fisher describes the Kuapp and Smith technic in the fifth chapter. The author describes fully his latest variation of the suction method for doing the intracapsular extraction. The seventh chapter is devoted to the methods of acquiring technic, chiefly by continued practice on kittens' eyes. The final chapter is by Nugent, on fitting glasses after operation. The book is concise and well illustrated and gives the student an outline of the various procedures used by well known ophthalmic surgeons but does not discuss the advantages and disadvantages of the different operations. The author does discuss the accidents that may occur during the operation but omits complications and sequelae that may occur after the surgical procedure. A chapter on the anatomic, physiologic and visual results in a series of operations by the various methods would add greatly to the value of the book to the student.

Medicolegal

Trauma Broken Compensation in Aortic Insufficiency and Diaphragmatic Pleurisy Attributed to Automobile Accident—The plaintiff was injured in an automobile collision due to the negligence of the defendant. He sued and was awarded damages in the amount of \$10,000. The defendant on appeal to the Supreme Court of Missouri admitted liability but contended that the damages awarded were grossly excessive and attributed the excessiveness to the action of the trial court in authorizing the jury to award damages for permanent injury.

Prior to the accident, the plaintiff had an aortic insufficiency which however, was fully compensated. As a result of the collision, he contended, there ensued a state of broken compensation producing permanent injury. The accident occurred July 14, 1928. The plaintiff returned to work the following Monday and thereafter lost only four days' work between the date of the injury and the date of the trial sixteen months later. The plaintiff testified that while he had heart trouble before the injury, it did not bother him. Following the accident, he suffered with shortness of breath. Exertion brought on nervousness and a state of exhaustion. At times he suffered pain. The physician appearing for the plaintiff testified that he examined the plaintiff just prior to the trial and found him suffering from a state of broken compensation and that it was possible for such a condition to be caused by a physical shock. He did not, however, testify that the plaintiff's condition was due to the collision. Another physician, appointed by the court to examine the plaintiff about a week prior to the trial testified that from his examination he believed that the plaintiff's heart was in a diseased condition before the accident and that plaintiff's condition at the time of examination could have been caused by trauma or by other causes. He expressed no definite opinion as to the cause. A medical witness for the defendant testified that the accident could not have permanently aggravated the condition of the plaintiff's heart. It is clear said the Supreme Court that a jury could not, except by pure guess and speculation find from the medical testimony that the accident permanently aggravated the plaintiff's heart condition. It is true, continued the court that the plaintiff testified that his heart did not give him any trouble before the accident but that a short time thereafter the symptoms of heart trouble manifested themselves. As a matter of course the plaintiff would know how he felt before and shortly after the accident but no layman would be competent to say what caused a heart condition. The sum total of the evidence in the opinion of the court was that the condition of the plaintiff's heart at the time of the trial might or could have been caused by shock or by the disease which the plaintiff had prior to the accident. If the heart condition was caused by disease the defendant was not liable therefor. Evidence that the condition might or could have been caused by either the accident or disease without any substantial showing as to which of the possible causes did produce the condition furnished no basis from which a jury could determine the cause.

The plaintiff further contended that he received a pleural injury which caused an adhesion of the pleura to the diaphragm thereby permanently impairing the right lung. The plaintiff

was injured shortly before noon. A physician examined him at his office between 3 and 4 o'clock the same day. This physician testified that a roentgenogram was made and revealed a diaphragmatic pleurisy. If this testimony is true, said the court the diaphragmatic pleurisy could not have been caused by the injuries received in the collision since it would not have developed in the few hours intervening between the time of the accident and the time the plaintiff was examined. The same witness, however, later on in his testimony testified that the pleurisy which the plaintiff had was the result of the accident and that it developed some time after the plaintiff was injured. This conflict in the physician's testimony, said the court, presented a question as to whether or not there was any substantial evidence tending to show that the diaphragmatic pleurisy was caused by the injuries the plaintiff received in the collision. Where a party to a suit relies on the testimony of a single witness to prove an issue, and the testimony of such witness is contradictory and conflicting one version thereof tending to prove the issue, the other tending to disprove it with no explanation of the contradiction, and no other fact or circumstance in the case tending to show which version of the evidence is true, no case is made, and the jury should not be permitted to speculate or guess which statement of the witness should be accepted. The court concluded that there was no substantial evidence tending to show that the diaphragmatic pleurisy which the plaintiff claimed permanently impaired his right lung resulted from the injuries received in the collision.

The trial court erred, therefore, in submitting the question of permanent physical injury to the jury for which error the judgment of the trial court was reversed and the cause remanded.—*Adelsberger v. Sheehy (Mo.) 59 S. W. (2d) 644*

Corporate Practice of Optometry Illegal in Iowa—The Kinky Optical Company, a Delaware corporation, was organized among other things, "to manufacture, purchase and sell optical goods and glasses of every character, mathematical and scientific instruments, photographic supplies, and materials, and carry on the business of opticians and dealers in optical goods and allied lines." It established equipped, maintained and operated, in various states, offices or departments where licensed optometrists were employed to carry on the practice of optometry. W. O. Jensen, a licensed optometrist, had been so employed by the corporation and had conducted and managed stores or departments for it in Minneapolis, Duluth, Kansas City, Detroit, Pittsburgh and Sioux City.

In August 1931, Jensen was sent by the corporation to take charge of an optical department owned by it in the Younker Bros. Department Store, in Des Moines, Iowa. An alleged lease was entered into between the corporation and Jensen, under the terms of which the former purported to lease to Jensen certain examination rooms or space located in the Younker Bros. Department Store and agreed to pay him \$281.66 per month. This so called lease provided that all eye examinations should be under the exclusive control of Jensen. Furthermore the corporation and Jensen entered into a written contract of employment, under the terms of which the corporation agreed to employ Jensen and to pay him \$240 per month plus certain percentages. This contract also provided that Jensen should be the manager of the optical department but that he should in all things be subject to the control and direction of the proper officers of the corporation. All money derived from the department was to be deposited in the name of the corporation in a bank selected by it and all disbursements were to be made by checks drawn by the proper officers of the corporation. All machinery and equipment installed and used in the department was the property of the corporation and all the accounts of the business were handled through the Younker Bros. store. The name of the corporation did not appear in any way in the business. Advertisements of the business appeared in local newspapers under the name of Younker Bros., such advertisements being prepared, however, in the home office of the corporation in St. Paul. They were inserted in the newspapers and paid for by the corporation. Contending that the corporation was practicing optometry without a license the state of Iowa sought an injunction to restrain such practice. The trial court refused to issue an injunction and the state appealed to the Supreme Court of Iowa.

The corporation argued that it was not practicing optometry, that Jensen, the licensed optometrist, was the lessee of the corporation and was not under its supervision or control in the practice of optometry, and that it did not profess publicly to be an optometrist nor did it assume the duties incident to the practice of optometry. It is true, answered the court, that the name of the corporation did not appear in connection with the business. The business was advertised in the newspapers in the name of Youmker Bros, but these advertisements were all prepared, inserted in the newspapers and paid for by the corporation. The ownership and control of the entire equipment was in the corporation not in the employee Jensen. Its officers determined all matters of policy and said the court the subtle attempt by the corporation to evade the provisions of the Iowa statute regulating the practice of optometry by employing a licensed optometrist to conduct its business and by the execution of the alleged lease was too patent to appeal strongly to a court of equity. The execution of the alleged lease in connection with the contract of employment was a sham and a fraud. Furthermore the court observed the Youmker Bros should have been made a party defendant in this action. The store had no more right to hold itself out to the public as being engaged in the practice of optometry than did the corporation. The corporation could not conduct the business without a license and it could not obtain a license. The court could conceive of no reason why the corporation should be permitted to continue its activities under the license of its employee. The trial court should have issued the injunction. The Supreme Court therefore reversed the decision of the trial court and remanded the case.—*State v. Kinds Optical Co (Iowa)*, 248 N W 352

Malpractice Negligence Provable by Lay Testimony

—While the defendant dentist was polishing a bridge in the plaintiff's mouth the polishing instrument slipped and cut her. She sued the dentist for malpractice and obtained a verdict in the trial court. The dentist appealed to the Supreme Court of Minnesota contending that there was no evidence on which the jury could base a verdict against him.

It was not necessary, said the Supreme Court for the plaintiff to establish her case by expert testimony for the cause of the movement of the dental instrument from the bridge to the tissues of the plaintiff's mouth was not a scientific question. In such a case the rule applied in *Evens v. Roberts* 172 Iowa 653, 154 N W 923, is applicable. In that case a surgeon in performing an adenoidectomy cut off a part of the patient's tongue. The court said:

If we understand counsel correctly it is their contention that negligence in cases of this nature can be established only upon the testimony of competent experts. What may be the rule where the sole question is upon the treatment of the diseased part and whether it was in accordance with approved and medical standards we need not here decide for as we have already noted this is not a case of that kind. The jury here did not have to consider whether the method of the defendant in removing the adenoids was correct or scientific but whether the unintentional wounding of plaintiff's tongue was occasioned by lack of reasonable care on his part. This it would seem very clear, involves no question of science or necessarily of expert knowledge.

Nor was it necessary in the present case continued the Supreme Court, for the plaintiff to prove that her negligence did not cause or contribute to the injury. After reviewing the evidence the court could not hold as a matter of law that the jury could not find that the defendant's negligence caused the injury. In the opinion of the court, however, the amount of damages awarded was too large and it therefore affirmed the judgment of the trial court only on condition that the plaintiff consent to a reduction in the amount awarded.—*Ellering v. Gross (Minn.)*, 248 N W 330

Wills Insane Delusions and Testamentary Capacity —

Derangement of mental faculties, says the Supreme Court of Missouri, does not incapacitate a testator from making a will, if the derangement does not render him incapable of transacting his ordinary business, of understanding the extent of his property or of appreciating the natural objects of his bounty. So, an insane delusion that will destroy testamentary capacity must be a delusion as to or affecting some matter necessarily involved in the making of a will, and not as to some extraneous or collateral matter or fact. An insane delusion is defined to

be a false and fixed belief not founded on reason and incapable of being removed by reason. One of the requisites of a sound mind in making a will is that the testator is able to remember and appreciate the natural ties of kinship. If it be shown that a person making a will is possessed of an insane delusion as to any person who is the natural object of his bounty which renders the testator incapable of appreciating and responding to the natural impulse toward such person then the testator lacks testamentary capacity.—*Hall v. Mercantile Trust Co (Mo)* 29 S W (2d) 664

Medical Practice Acts Collateral Attack on Order of

Revocation of License—The department of registration of Utah revoked Cragun's license to practice medicine, and his appeal to the Supreme Court of Utah was dismissed on the ground that a direct appeal could not be taken from the department's order to the Supreme Court. *Harrison v. Cragun* 78 Utah 445 3 P (2d) 1092. Subsequently Cragun was convicted of practicing medicine without a license and he again appealed to the Supreme Court of Utah. He sought to justify his right to practice medicine by contending that the complaint on which the department revoked his license was insufficient and that therefore the order of revocation was void. This contention, however, said the Supreme Court of Utah, constitutes a collateral attack on the order of revocation and to meet the contention it need only be shown that the allegations of the complaint tend to show, or colorably or inferentially show each material fact necessary to a cause of action. Defects or imperfections in the complaint which on its face is amendable cannot be urged to invalidate the order. If on the other hand the complaint is not only defective with respect to essential averments but is also so wanting in substance as not to be even colorable or amendable the order founded thereon is not only subject to direct but also to collateral attack. Assuming said the Supreme Court that the complaint in question would not withstand a direct attack yet on its face the complaint, charging Cragun with having attempted to procure or having aided and abetted in procuring a criminal abortion, stated enough to have informed him, not only of the nature of the wrong but of the particular instance or the alleged perpetration. The fact therefore, that the complaint did not charge that the attempt to procure a criminal abortion was on a pregnant woman that it did not allege the means by which the abortion was attempted that the intent with which the abortion was attempted was not stated and that it was not negatived that the abortion was necessary to preserve the life of the woman, may not be urged in support of a contention that the order of revocation was void when that contention is made in a collateral attack on the order. The judgment of the trial court convicting Cragun of practicing medicine without a license was affirmed.—*State v. Cragun (Utah)* 20 P (2d) 247

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Surgical Measures Facilitating Radium Implantation—Sharp states that irradiation may fail to control epidermoid cancer of the head and neck because of the omission of certain aids, chief of which are various conservative surgical procedures. Many tumors require both external and interstitial irradiation to produce cure. In such cases, surgical measures are indicated for exposure and drainage and for dealing with complications in adjacent bony structures. The removal of the bulky, raised portion of a skin tumor for example may make more effective irradiation of the active base possible, while exposure of deep-seated growths is an aid to the accurate implantation of radon seeds, as in early neoplasms of the nasal accessory sinuses. A justifiable substitute for radical neck dissection in metastatic carcinoma of the neck consists in exposure and the implantation of gold-filtered radon seeds. The reduction of inflammation in tumor-bearing areas may be accomplished by a group of conservative surgical procedures which facilitate drainage, as by enlarging the opening or by removing the greater part of the irradiated area. Resection of bone secondarily invaded by cancer is advised because of its radioresistant character. The author discusses in detail carcinoma of the skin, lip, tongue, floor of the mouth and nasal accessory sinuses, intrinsic carcinoma of the larynx and epidermoid carcinoma metastasis in the neck.

Chronic Idiopathic Hypochromic Anemia—Mettler and his associates discuss the relationship of diet and nutrition to anemia in ten cases of chronic idiopathic hypochromic anemia associated with hypochlorhydria or achlorhydria and defective diet. The response of the bone marrow, as determined by the hemoglobin and production of erythrocytes, to iron administered in large daily oral doses in the form of iron and ammonium citrate (U S P) was compared to the response in patients on an 'iron-rich' diet. In addition, a comparison was made of the response of the bone marrow to a diet rich in iron and to a meal previously digested in vitro with hydrochloric acid and commercial pepsin. The bone marrow responded rapidly and excellently to large doses of inorganic iron but there was no evidence of increased hematopoiesis after the ingestion of an 'iron-rich' diet for a long period of time. There was however, a rapid and satisfactory increase in the concentration of the hemoglobin, and in the production of red cells and a slight reticulocyte response following the administration of predigested meals. The authors conclude that chronic idiopathic hypochromic anemia is presumably due to a deficiency of iron wherein gastric dysfunction leads to failure in utilization of organic (dietary) iron.

Fetal Endomyocarditis—Farber and Hubbard collected ten cases of fetal endomyocarditis from the literature to which they have added four of their own, in all of which there is evidence indicating that the cardiac changes can best be explained on the basis of an infectious process originating in intra-uterine life. In the cases gathered from the literature, there were eight deaths within the first four days of life. Of their own patients two died within the first three days, one lived two and one-half months and the other five months. In the two latter cases there was clinical evidence of heart disease since birth. The most frequent observation throughout the series was cyanosis. Death often occurred unexpectedly. The authors heard a murmur in only two of their patients, and only once was the heart enlarged to percussion. In the other two the hearts were clinically recorded as normal. The cardiac abnormalities represented the end-results of old inflammatory processes. The most important are the gross distortion of the valves and the thickening of the endocardial surfaces and the microscopic evidence of previous infection, such as fibrosis and calcification. There was aortic stenosis in seven of the total series. Five of these also showed changes in the mitral valve. One had pulmonary stenosis with a superimposed terminal acute bacterial endocarditis. In all the instances of stenosis, the appearance of the leaflets resembled the changes found in chronic valvular disease of later life. Aortic atresia occurred four times and pulmonary atresia once. In only one case were all the valves recorded as normal but there was scarring and calcification of the myocardium. In four cases, calcium deposits were found in the myocardium. In considering the etiologic possibilities it is important to exclude congenital syphilis. In a few instances the mother contracted an "influenza" type of infection in the seventh or eighth month of pregnancy. It has been claimed that this was responsible for the cardiac changes in the infant. It would appear profitable, as soon as a diagnosis of congenital heart disease is suspected to make a careful review of the health of the mother during pregnancy.

Aseptic Uretero-Intestinal Anastomosis—Higgins outlines a technic for simultaneous bilateral transplantation of the ureters into the rectosigmoid in which the continuity of the ureter is not interrupted until the new channel develops and the normal physiologic function of the upper urinary tract

is not altered until the anastomosis has formed. Owing to the simplicity of the procedure the operation may be performed on a child with extrophy of the bladder very early and before renal complications develop. The author reports a case in which the operation was performed on a boy, aged 4 in whom a most satisfactory result was secured with slight postoperative reaction. Examinations of the kidneys and ureter in dogs six months after this operation reveal no evidence of hydronephrosis or infection. Experience with experimental animals has shown that peritonitis, shock and acute renal sepsis following this procedure are reduced to a minimum.

Osteopexilia—Bloom describes a case of osteopexilia in an adolescent of 17 who complained of recurrent attacks of sore lids since he was 3 years of age. He is blind in the right eye. He presented many cardinal symptoms of congenital syphilis such as saddle nose, Hutchinson's teeth, enlarged epiphyses of the wrist, rather thin pronounced costoclavicular joints and wing scapulae. In addition he had blepharitis, phthisis bulbi and complete atresia of the right side of the nose. The Kahn test was negative. The mother gave a history of numerous miscarriages and one stillbirth. The father is confined to an institution. The living siblings are a sister who is five years older, a sister who is three years younger, a brother four years younger and another sister seven years younger. The Kahn test was negative in all but the spinal fluid curve in the younger brother slightly resembled a tubercle curve. The diagnosis in the case was blepharitis, congenital syphilis and juvenile dementia praecox with tabes. Roentgenograms showed that there were numerous areas of increased density varying in size from 1 to 15 mm in the carpal, metacarpal and phalanges, the heads, upper half of the shaft and lower ends of the humeri, the scapulae and the upper and lower ends of the radius, ulna, tibiae and fibulae. There was one single spot 5 mm in diameter in the middle of the right clavicle and one 3 mm in diameter in the left jaw. The spine, ribs and skull were not affected. No changes were found in the mother, the two younger sisters and a younger brother, except in the case of the next youngest sister in whom a single spot 2 mm in diameter was found at the base of the second metacarpal of the left hand.

Treatment of Gonorrheal Arthritis—In the experience of Hedrick, aspiration and air insufflation of the knee is the method of choice in the treatment of the serous type of gonorrheal arthritis. Repeated insufflations may be done if the case is refractory but frequently one is sufficient. For the periarthritis and pro-arthritis immobilization of the affected joint is nearly always necessary because of the associated pain. This is done best in plaster if possible. Failing this splints are used. The pro-arthritis should be drained or irrigated as soon as recognized. Ammonium iodody benzoate is started as soon as the diagnosis is made. After a series of six biweekly injections it is stopped but may be resumed again after two or three weeks. A second series is not often necessary. In mild cases the use of ammonium iodody benzoate in outpatients permits patients to be ambulatory. After the symptoms have subsided the plaster is removed and active motion, together with diathermy and massage is instituted. Hyperpnea by fever diathermy is useful especially in refractory cases. The author feels that the use of these measures materially shortens the course of the gonorrheal arthritis, prevents massive destruction of the joint and permits more complete restoration of function than measures he has known heretofore. If an acute or chronic urethritis is present it should be treated actively.

Interphalangeal Osteochondromatosis—Mandruzzato presents the first case of interphalangeal osteochondromatosis and states that the etiology and pathogenesis of osteochondromatosis is still uncertain. From the histologic study and its clinical evolution it can be classified as a new formation of benign character from a metaplasia distinctly different from an arthritic alteration. As a summary of the published cases, the most salient features are reported as follows. The disease is noted in young, robust persons in 50 per cent of whom there is a slight history of trauma. It is slow in its course, latent and unrecognized by the patient until late, when there is pain or functional disturbances. It is usually monoarticular and has a particular predilection for the large joints such as the knee and the elbow. The osteocartilaginous bodies can be present

at the same time in the articular bursae. They have been found also in the tendon sheaths of the flexor group of the hand. The joint is full of bodies of different sizes and shapes. The synovial membrane is hyperemic and covered with fibrous exudate. The bony extremity is almost always intact. The histologic examination in the author's case revealed hypertrophic and hyperemic villi, villi transformed into pedunculated bodies and loose bodies. Breuckman believes that these formations become secondarily pedunculated and become ossified by either the fluid or the membrane.

Painless Histamine Skin Test—Perlow presents a table which reveals that the size of the reaction and the intensity of the pain vary directly as the concentration of the histamine when used alone. To prevent the pain, correspondingly stronger solutions of procaine hydrochloride are necessary. He has found that 1 2,000 histamine in a 0.5 per cent solution of procaine is such a solution. The test is painless and the reaction in the skin is intense and rapid enough to be practical. There was no noticeable difference between the reactions following injections of 1 1,000 histamine and those produced by 1 2,000 histamine in a 0.5 per cent solution of procaine. Skin with deficient circulation reacted as intensely to 1 2,000 histamine in a 0.5 per cent procaine solution as it did to 1 1,000 histamine alone. The reaction may be read at five minutes but is best read at ten minutes, when it is at its height.

Administration of Magnesium Sulphate in Hypertension—Zohman and Sternberg observed that the parenteral administration of magnesium sulphate had a distinct effect in reducing the systolic pressure in forty of a series of fifty consecutive cases of hypertension. The effect was sustained for a period of at least two weeks. The parenteral administration of magnesium sulphate had a definite effect in reducing the systolic pressure in twenty-five cases and the effect was sustained for a period of two weeks in twenty-one cases. The parenteral administration of magnesium sulphate had a distinct ameliorating effect on the symptoms of hypertension, viz., headache, vertigo, insomnia, hot flashes, head noises and nervousness. In order to reduce the factors of error the authors employed a standardized procedure. 1 Blood pressure readings were taken three times a day for a period of a week in all hospital cases. On the outpatients one single reading was taken each morning at the same hour for a period of a week. 2 All injections were given at a definite hour in the morning. Ambulatory patients rested in the supine position for a half hour before receiving the injection. 3 Blood pressure readings were made one, two and three hours after the injection at the same hour in the morning for at least two weeks. 4 Three blood pressure readings were taken at five minute intervals. The first reading was discarded and the mean reading of the other two was taken to be accurate. The authors used chemically pure, anhydrous magnesium sulphate in triple distilled water. A

stock solution of 25 per cent by weight was prepared. All dilutions were made from this immediately before using by adding warm, sterile, triple distilled water. A graduated arsphenamine cylinder was used with a length of rubber tubing ending in an adapter for a luer needle. The rubber tubing was interrupted at a point 12 inches from the needle by a petcock so that the flow could be interrupted. A 20 gage needle of 2 inches was used. The level of the fluid in the cylinder was kept at approximately 18 inches above the anterior chest wall of the patient at all times. The solution was warmed to body heat and was delivered to the patient intermittently in accordance with the sensation of heat experienced by the patient. The rate of flow of the solution was approximately 100 cc in half an hour. The patient remained at rest in bed for two hours after the injection.

Transitory Baldness Following Trauma—Ronchese presents a case of a peculiar type of sudden and transitory baldness presenting features both of alopecia areata and of alopecia diffusa, a traumatic transitory alopecia of male pattern in a woman. The baldness was evidently not hypocratic, because of the history of a sudden development and a quick recovery. This was a case of alopecia following a trauma which is rare in general and unique with this pattern not having been recorded in either sex. The distribution of alopecia resulting from nervous shock is usually described as in patches or completely diffuse, but not limited to the top of the head. The usual time from the shock to the falling of the hairs is from a few days to a few weeks. In the present case the time was about four months although not only the wound itself but the subsequent complications must be taken into consideration as the acting cause. The author calls attention to the disproportion between the relatively slight trauma and the conspicuous loss of hair and also to the psychic condition of the patient. Apparently there was a trophic nervous reaction of a distinctly reflex nature. The patient has an infantile uterus and coarse hairs on the chin and lips. A dysfunction of the sexual glands may be considered a tentative explanation of the unusual pattern. Pituitary was not administered and hence cannot be credited with the quick recovery, and psychotherapy could not be attempted.

Nickel Eczema—Goldman describes the cases of two nickel workers with definitely proved nickel eczema. In each the eczema developed after a brief period of contact, two days in one case and three days in the other. These patients exhibited a remarkable idiosyncrasy to the nickel ion. Both gave negative reactions to cobalt solutions and to lime. Both patients experienced previous allergic disturbances, urticaria in one instance and hay fever in the other. One patient exhibited a strong reaction to a nickel coin. The author discusses the practical value of nickel coins and nickel-plated objects as potential eczematogenic agents and suggests that these be considered in the study of some of the eczemas of the hands with heretofore unknown etiology.

Vitamin A Deficiency—Loewenthal believes that the medical literature has been reticent regarding the changes in the skin in avitaminosis. The only description of the lesions that he can find is that of Pillat. Pillat's cases and the author's, however, agree in only a few particulars. In both the skin is dry and scaly, and in both there are comedones on the face and chest. Here however the resemblance ceases, Pillat's

dermatitis is a decay, associated with a diminished resistance to pyogenic bacteria and consequent multiple abscesses. The condition in the author's cases is a dyskeratosis, with changes consequent on this condition and without signs of sepsis or softening. What, then, are the true dermal manifestations of vitamin A deficiency? Though always referred to as the anti-infective factor, there is little evidence of detail that vitamin A subserves such a function in man. The formation of leukocytes, bacteriolysins, precipitins and the like seems to continue normally in spite of an avitaminosis. It is probable that the infections which occur in some cases of vitamin A deficiency are due to breaches in epithelial surfaces permitting a more than normal invasion of bacteria with which the normal defense mechanism of the body is unable to cope. If Pillat's patients were subject to general undernourishment as well as to a specific deficiency in vitamin A, this would explain the differences between his observations and those of the author. The author's cases would then represent the dermatosis of vitamin A deficiency, while those of Pillat would have superimposed the results of general undernourishment and possible deficiency in other necessary food factors and neglect of long standing.

Carbohydrate Metabolism and Rhythmic Functioning of the Liver.—Mollerstrom states that in many cases of diabetes there is a periodic variation in the effect of nourishment on the blood and urine sugar curves, irrespective of meals. At certain hours of the day, postalbuminuric hyperglycemia is milder and less prolonged and the excretion of sugar in the urine diminishes. There may be a tendency to spontaneous reduction of the blood sugar content, so that, in spite of nourishment blood sugar values are sometimes obtained which are less than the starvation values. The endogenous periodicity is different in different persons and may change slightly from one day to the next in the same person. This phenomenon is explained by Forsgren's discovery of the rhythmic functioning of the liver with alternate production of glycogen and secretion of bile. In the assimilatory stage of the liver function with glycogen production there is a tendency toward carbohydrate retention in the body with reduction of the blood sugar content and of the excretion of sugar in the urine, in the dissimilatory or secretory stage the conditions are reversed. The endogenous periodicity of the carbohydrate metabolism is significant for the results of alimentary tolerance tests in diabetic patients, and appears to be of fundamental importance in the development of a rational insulin therapy. Insulin should be administered with due regard for the endogenous rhythm, and not for meal hours.

Vasodilatation in Lower Extremities.—Landis and Gibbon immersed the forearms of patients in warm water (from 43 to 45 C.) for thirty-five minutes in order to produce vasodilatation in the lower extremities. They studied this vasodilator response in twenty-four patients who showed clinical evidence of peripheral vascular disease. The authors conclude that the procedure is a simple and entirely unobjectionable method of producing vasodilatation in the lower extremities. If the surface temperature of the toes rises above 31.5 C. (88.7 F.), significant obliterative structural disease of the arteries of the lower extremity is definitely absent. If the

surface temperature fails to rise to this level, organic arterial obstruction is probably present. With controlled room temperature, the approximate grade of the organic obstruction is indicated by the difference between 31.5 C. and the maximal temperature reached. For absolute certainty in the diagnosis of organic arterial obstruction the abnormal vasodilator response obtained by warming the forearms should be confirmed by some other method of producing peripheral vasodilatation.

Effect of Alkali on Absorption of Thyroxine.—Thompson and his associates observed that in three patients suffering from myxedema, single doses of 7.5 and 10 mg. of synthetic thyroxine in an alkaline solution had from 68 to 80 per cent as much effect on the basal metabolism when administered by mouth as when injected intravenously, in terms of the increase in basal metabolism, and from about 72 to 84 per cent as much effect in terms of excess calory production. The same doses given by mouth in the form of the monodism salt to two patients had only from one third to two fifths as much effect as an alkaline solution given by mouth. In one patient a single dose of 10 mg. of pure synthetic thyroxine by mouth produced too slight a change to be measured. The solubility of any thyroxine compound administered appears to play an important part in its absorption from the gastrointestinal tract and hence in its effect on the basal metabolism. In two of the patients the intravenous injection of synthetic thyroxine produced approximately the same increase in basal metabolism as an equal dose of natural thyroxine.

Alcohol Injected Intravenously.—According to Mehrtens and Newman, the intravenous administration of alcohol is admirably adapted to the study of the psychologic effects of alcohol on man. After a single dose is administered intravenously, the alcohol in the lumbar spinal fluid rises much more slowly than that in the blood attains its maximum later and declines more slowly. When the alcohol in the blood is kept at a constant level for from four to five hours, the alcoholic content of the lumbar and cisternal fluids at the end of this time is equal to, or in excess of, that in the blood plasma. The evidence from this work seems to indicate that alcohol enters the spinal fluid by diffusion from the blood, probably largely from the choroid plexuses. The higher alcohol content of the spinal fluid as compared with that of the blood plasma may be due to a relative impermeability of the absorbing system to alcohol, with a resulting concentration of the alcohol, or to an active secretion of the alcohol by the choroid plexus. The authors favor the former hypothesis.

Local Anesthesia in Labor—Tripp states that procaine infiltration of the perineum relaxes the muscles and eliminates that period of anguish when the child's head passes through the vulva. In every case infiltration is done for that one reason alone, even if episiotomy is not necessary. He believes that rigid muscles tear more readily than relaxed ones. Uterine contraction pains are not affected by the infiltration. Sodium amylal, amylal or amytal compound greatly reduces the amount of pain from contractions, and the author recently used amytal compound with satisfying results. Amytal compound supplies an analgesic of unsurpassed value with the exception of the opiates, and it supplies a sedative and hypnotic of accepted value. Barbituric acid derivatives counteract the ill effects that sometimes accompany the use of procaine hydrochloride. The technic employed is as follows: A 5 per cent solution of mercurochrome is used to prepare the patient after she has been cleansed with a weak compound solution of cresol and to irrigate the vagina. In the stage of labor, when the contractions are becoming painful, one capsule of amytal compound is given by mouth and is repeated in one hour if the pains are still severe. When the child's head begins to make pressure on the perineum, about 20 cc of a 1 per cent solution of procaine hydrochloride is injected into the perineum. The first injection is made into the perineal body with about 5 cc of the solution, the needle being long enough to go past the skin and fat, so that the solution is placed in the muscles. From this point the bulbocavernosus muscles are injected. A few cubic centimeters is also injected posteriorly to both sides of the perineal body in order to catch the fibers of the superficial transverse perineal and levator ani muscles. If episiotomy is to be done the skin of the corresponding area is infiltrated. The author states that with this technic he has been able to conduct labor practically without pain and with the cooperation of a quiet and calm patient.

Pheдрine in Allergic Migraine R H Kampmeier New Orleans—p 74

Preservation and Preparation of Pollen Extracts—According to Rappaport ragweed pollen extract may be dried at 40 C with little loss in its solubility and no demonstrable change in its potency. A highly concentrated pollen extract may be prepared by redissolving the dried material in a smaller quantity of water than that used for the original extraction. The most concentrated solution prepared contained 18 mg of nitrogen per cubic centimeter the equivalent of an 18 per cent pollen extract. The concentrated extract prepared in this manner had a potency which was proportional to its nitrogen content when compared with the original undried material. The dried material showed no loss of activity when redissolved

after eighteen months. The chief advantage of this method of preparation and preservation of pollen extracts is that it provides a readily available supply of pollen stock, which is preserved by drying and which can easily be made into a solution of a definite potency.

Rapid Standardization of Protein Extracts—Cohen and Goodale describe a method of nitrogen determination applicable to protein extracts in which the protein extract is diluted with distilled water so that 1 cc of the solution will equal approximately 0.1 mg of nitrogen per cubic centimeter. After the extract is properly diluted, 1 cc of extract and 1 cc of digestion mixture (sulphuric-copper sulphate mixture or phosphoric-sulphuric mixture) are placed in a digestion tube. This is heated slowly on the micro-bunsen burner until the water boils off and white fumes appear, and then the tube is covered with a watch glass. The heating should continue until the solution first chars and then becomes clear white, when it is allowed to cool for thirty seconds, after which about 5 cc of distilled water and then 1 cc of 10 per cent solution of potassium and sodium tartrate is added drop by drop. Distilled water is added up to the 35 cc mark. At this point the tube may be corked and kept in a refrigerator for twenty-four hours, if desired. In reading, the standard consists of 1 cc of standard nitrogen solution, 1 cc of digestion mixture, distilled water up to the 35 cc mark, and 15 cc of Nessler's solution, mixed by inverting the tube. To the extract 15 cc of Nessler's solution is added and read against the standard in a colorimeter preferably by daylight. In the calculation, the colorimeter reading of the standard over the colorimeter reading of the extract $\times 0.1$ (amount of nitrogen in standard) \times dilution = milligrams of nitrogen per cubic centimeter of extract.

Blood Catalase in Heart Disease—Healy and Baker studied the diagnostic value of the blood catalase in disease of the heart. They observed 429 cases and checked the amounts of oxygen liberated by the individual bloods. The examination of 136 apparently normal persons showed the normal range to be from 10 to 15 cc of oxygen. When a blood caused a 19 cc yield, it was repeated to be certain that it was not a borderline case and its proper classification ascertained. The average normal figure was found to be about 15 cc, thus putting all the normal cases in the 10 to 20 group. There were 116 cases of mitral and aortic valvular disease of rheumatic

etiology, a few of which were decompensated. All these were felt to be inactive valvulents as determined by the general clinical picture of each case and observation over a period varying from weeks to years. At first examination and others after close study the average yield was 29 cc in these. A value of from 21 to 30 indicates valvular disease, the final diagnosis being dependent on the entire clinical and laboratory picture. At about the age of 26 the lesion is probably active and at the age of more than 30 certainly active. The authors conclude that the determination of blood catalase is of value in making a diagnosis of rheumatic heart disease especially in doubtful cases. It is of help in determining the activity or inactivity of a lesion of the valve. A study of the blood catalase in active rheumatic endocarditis will aid in determining the length of time required for treatment.

Methylene Blue for Aniline Dye Poisoning—Williams and Chellis describe a case of aniline dye poisoning in a student who had been handling parabromaniline and parabromorthosulphanilic acid. Intense signs and symptoms of pigmentation of the skin, headache, stupor, nausea and vomiting were relieved promptly by the intravenous injection of a 1 per cent solution of methylene blue (methylthionine chloride U. S. P.). It was shown by spectroscopic studies of the blood that the poisoning was due to parabromaniline and that the parabromorthosulphanilic acid was nontoxic when applied to the skin. Animal experiments indicated that methylene blue injected intravenously into a rabbit in approximately twice the strength of that given to the patient did not affect the absorption spectrum of normal blood but that if methylene blue is mixed with normal blood in vitro the spectrum from such a mixture seems to be a composite of the spectrums of methylene blue and normal blood.

Improved Method of Blood Culture—Munk and Snelhof state that the following method of making blood cultures has given satisfactory results. A bottle approximately 250 cc in size and containing 30 cc of dextrose phosphate broth is fitted loosely with a two hole rubber stopper bleeding attachment the inlet tube of which should extend for about 6 cm into the bottle to which a number 13 gauge needle is attached and is sterilized at a pressure of 15 pounds for thirty minutes. Just before use 10 cc of sterile peptone solution containing 2 drops of a 5 per cent solution of sterile sodium carbonate is added. The rubber stopper is then fitted tightly and tied into position. Into this bottle approximately 130 cc of blood is drawn from a suitable vein. The bottle is left to stand at room temperature for three hours in order to secure a firm adherent clot incubated at 37 C, and examined carefully each day for the growth of small pinpoint colonies on the edge of the clot or in the surrounding fluid. For identification of eventual growths, streaks on suitable mediums can be made. Using this method the authors obtained positive cultures in forty-three of sixty-seven cases (64 per cent) while the usual routine method yielded positive blood cultures in only fourteen cases (21 per cent).

Irritation and Toxicity of Iodobismutol—Hanzlik and his associates point out that the local irritant action of iodobismutol prepared with propylene glycol and injected intramuscularly in human subjects appears to be about the same as ordinary iodobismutol or possibly somewhat more in some subjects. According to mortality statistics from intravenous and intramuscular injections in animals iodobismutol prepared with propylene glycol is less toxic systemically than is ordinary iodobismutol prepared with ethylene glycol. Iodobismutol prepared with diethylene glycol tends to be more toxic than ordinary iodobismutol. The presence of iodide in iodobismutol tends to increase the toxicity as indicated by fatal doses in animals, but this is not important in the practical utility of iodobismutol nor is the systemic action of ethylene glycol, in ordinary iodobismutol in large repeated therapeutic doses toxic or injurious, the margin of safety being ample.

Evolution of Mastoid Tip Cell—Almour presents a study based on the dissection of and experimentation with twenty-four well pneumatized temporal bones. In all the tract from the middle ear to the tip cell was demonstrable. It is conceivable that the tip cell may be pneumatized while the remainder of the mastoid process is sclerotic or diploic. This additional pathway from the middle ear into the mastoid process is of significance in that infection can spread by contiguity from the middle ear into the mastoid cells without spreading from the antrum. It explains the early appearance of tenderness over the mastoid tip in cases of acute purulent otitis media. This point of tenderness may be the only one present during the entire course of the disease. It also explains the frequent observation on roentgen examination of intact cells in the region of the antrum and throughout the major portion of the mastoid process in the presence of tenderness of the tip. It also accounts for isolated empyema of the mastoid tip cells with intact cells through the remainder of the mastoid process. It may also account for the presence of early facial paralysis in infants, since the pathway into the tip from the middle ear surrounds the facial canal, and for the early involvement of the jugular bulb by a thrombus.

Vaccine in Treatment of Arthritis—Rogers feels that it is definitely proved that rheumatoid arthritis is a bacterial disease and that it is fair to assume that osteo-arthritis is also a bacterial disease in which trauma plays a part. The menopause, obesity, thyroid deficiency and other conditions may be associated and aggravating. Climate through infection plays a part. The changes that occur in and about the joint may be due to the presence of the bacteria and their toxins or they may be allergic manifestations. The removal of foci of infection is important and should be done early. By the time a case of chronic arthritis has become well developed, the organisms have spread throughout the body and it has become a systemic disease. Removing an infected tooth or tonsil at this stage is like cauterizing a chancre to cure syphilis. No known medication will destroy these organisms without destroying their host. The greatest hope lies in building up the patient's resistance, that is, immunizing or desensitizing or both. The question as to whether the condition is type or group specific is important. If it is group specific a stock vaccine should be satisfactory, if type specific an autogenous vaccine from carefully collected cultures must be prepared. The author has observed not infrequently that a stock vaccine will be relatively impotent while an autogenous vaccine will be extremely potent. Cultures should be from all suggestive foci of infection: blood, throat and tonsils, nasopharynx, sinuses, abscessed or devitalized teeth, duodenal contents, stool, intestinal wall, urine, prostatic secretions, neck of the uterus and other sources. Each organism that is arthritis producing and all organisms to which the patient is sensitive are used to make up his vaccine and a group of organisms is added which have proved most potent in previous cases. The vaccine is given subcutaneously at intervals of from five to seven days. The dose is kept small as compared to the dose of commercial vaccine.

Surgery in Intractable Pain—Grant points out that the pain from cancerous lesions about the mouth and face, especially when the disease involves the lip, nose, maxillary antrum or

dorsum or side of the tongue, may be completely relieved by injection of alcohol into the second or third division of the trigeminal nerve or by section of its sensory root behind the ganglion. And not only is the pain from the cancerous lesion itself relieved but also radical methods for its removal are painless. These patients willingly accept fulguration, excision, implantation of radium or other treatment up to the limit of tolerance, because of their freedom from pain. Patients having malignant disease in this region are often encountered who are suffering severe and constant pain and who dread further or more intensive treatment because it aggravates their suffering. The author is certain that some of his patients who are alive at the end of five years survived because their freedom from pain permitted them to sleep to eat comfortably and to receive the maximal amount of treatment without an increase in their distress. It should be stated that the pain from malignant disease involving the floor of the mouth or the tonsil with pain referred to the throat or deep in the ear is not benefited by injections of the trigeminal. Occasionally a suboccipital craniectomy with section of the fifth and ninth nerves and the upper three cervical posterior roots has been attempted but the relief afforded has never been nearly as satisfactory as in those instances in which the lesion lies completely within the sensory distribution of the fifth nerve.

Use of Calcium in Pregnancy—White has been using calcium gluconate and dicalcium phosphate in all pregnant patients who complain of tingling and numbness of the hands and feet or cramping of the legs. There has been absolute relief of these symptoms in two or three days without the addition of any other kind of therapy. He found that the use of this type of calcium is of considerable value in many cases in which there is insomnia, pain and stiffness of the hips and at times, in general malaise associated with nervousness and irritability. He has made no effort to differentiate between polyneuritis of pregnancy and the tetanoid syndrome or calcium deficiency. He is of the opinion that the milder types of polyneuritis as they are commonly described may be due to calcium deficiency.

Preliminary Surveys of the Industrial Environment J. J. Bloembergen—p. 1343

Experimental Encephalitis—Muckenfuss and his associates state that their studies on the experimental transmission of encephalitis have been successful in seven of fifteen animals. Successful transfers were secured by making heavy inoculations (from 15 to 2 cc) of a thick brain emulsion intracerebrally, combined with from 5 to 10 cc of the same emulsion intraperitoneally. The inoculations were repeated after an interval of from four to five days. The symptoms observed in monkeys while varying in degree were uniform in character and suggested those seen in human encephalitis. The first significant symptoms appeared in from eight to fourteen days following the first inoculation and began with an elevation of temperature which tended to rise on successive days to a height of from 40.6 to 41.6 C (104.9 to 106.7 F) on the fourth or fifth day of the fever. When undisturbed the animals usually sat hunched up with their eyes closed as if asleep and with the head bent forward. When disturbed the animals seemed alert and often excitable. Intention tremors, most noticeable in the forelegs and in the head, usually appeared about the second or third day and were often pronounced. Muscular weakness of one or more extremities and occasionally definite paralysis made their appearance during the febrile stage. Involvement of the muscles of the eyes was not observed. The appetite usually continued good and the animals would often eat greedily throughout the febrile period. Constipation was often present. The spinal fluid at the height of the fever was usually under increased pressure, was clear and commonly showed cell counts of from 150 to 350. The animals were usually killed for transfer from the second to the fifth day of the fever but in a few instances the disease was allowed to run its course. In these instances the monkeys recovered completely. There were no spontaneous deaths, although some animals were apparently very ill when killed. The authors have successfully carried three strains through five passages in monkeys with incubation periods varying from eight to twenty-one days. Only about 40 per cent of the inoculated monkeys developed symptoms. The acuteness of the illness in animals coming down during the fourth and fifth transfers suggests that the virulence may be increasing. The pathologic picture is consistent with that seen in human beings during the epidemic and includes marked congestion with perivascular round cell infiltration together with some nerve cell destruction scattered diffusely through the brain bulb and cord. The virus persists in 50 per cent glycerin for at least one week.

Treatment of Tuberculosis of the Spine—Kite states that the merits of the nonoperative and the operative methods of treatment of tuberculosis of the spine cannot be accurately determined from a study of the conflicting statements in the literature. The important question for each surgeon to decide is which method will give him the better result in his own particular climate and with his individual operative ability. Spontaneous fusion of the diseased vertebral bodies, which is nature's method of curing the tuberculosis occurred in only 2 per cent of the cases. The deformity should be corrected as much as possible before operation. Absolute immobilization is the most important prerequisite in the treatment of any tuberculous lesion. No type of mechanical support will give absolute immobilization. This can be obtained for the diseased bodies of the vertebrae only after the posterior portion of the vertebrae have been firmly ankylosed by bony fusion. In evaluating the results one must distinguish between adequate and inadequate operations. All cases having an adequate operative fusion showed a solid bony ankylosis of the diseased bodies about three years after operation. Great care should be exercised to prevent operative shock, as tuberculous patients do not undergo operation as well as healthy patients. Besides the immediate risk there is the additional hazard of lowering the patient's resistance and thus disposing him to a flare up later of tuberculosis elsewhere in the body. For this reason it is recommended that if more than two vertebrae are diseased the operation be done in two stages and under local anesthesia. Bony fusion in the operative area and bony ankylosis of the diseased bodies occur as rapidly in children as in adults. Mechanical support should be continued until the diseased bodies show solid fusion. The results in forty cases treated by the nonoperative method were: excellent one, satisfactory seven, somewhat improved fourteen, unimproved eleven, and deaths seven. The results in fifty cases treated by the same method plus operation were: excellent in thirty-four cases having adequate operation or 100 per cent. In the fifteen cases having inadequate operations they were: excellent one, satisfactory six, poor six, and deaths two. There was one operative death. While operation does shorten treatment it affords no excuse for neglecting to use everything of value in the con-

servative treatment both before and after operation. Operative fusion is done only to cure tuberculosis and thus it will do in most cases if an adequate operation is done and if adequate postoperative treatment is given.

Localizing Small Stones in Kidney Substance—Turley uses a rectangle made from number 24 silver wire, 45 cm long and 25 cm wide, as an aid in localizing small stones in the substance of the kidneys. All intersections were lightly soldered to reduce their shadow casting to a minimum. The two wires forming the short ends of the rectangle are left long enough to encircle the kidney and fasten firmly if desired thus insuring accuracy of location. The device divides the kidney into nine sections. Behind the delivered kidney a small roentgen film well covered with a sterile slip is placed and exposure made. The marker is left unmolested until the film is developed. Comparison is immediately made with the marked kidney and the definite location of the stone obtained. Then, by using a straight needle first, or direct incision over the stone, the stone is removed with a minimum of damage to the substance of the kidney. The wires are very pliable, so that the application is quickly and easily made with no damage whatever to the kidney.

Reduction of Dislocated Shoulder Joint—Hardy describes a procedure that has been 100 per cent satisfactory in reducing twenty-five cases of uncomplicated dislocations of the shoulder. With the patient lying down the operator being directly behind the patient's head, grasps the elbow with one hand, supports the forearm with the other and abducts the arm while maintaining gentle traction in the direction of the long axis of the humerus in the same plane until the elbow is above the head and the arm close to the ear. This maneuver immediately relieves the pain that is caused by pressure of the head of the humerus on the periarticular structures. In this position the traction is increased, sometimes with slight to and fro rotation until the head of the humerus slips into position. If the muscles of the anterior and posterior folds of the axilla are spastic and the patient is muscular the wrist or hand may be steadied under the arm of the operator and the other hand used to massage the muscles to encourage relaxation. Backward and upward dislocations or the head of the humerus are easily reduced with downward traction and slight to and fro rotation. In order to make the mechanics of the subdislocations the same as the upward and backward dislocations the position of the shaft of the humerus is reversed.

Pneumococcal Arthritis—Fagge believes that, as soon as a suspicion of acute arthritis is tenable, the joint should be immobilized and, if distended, aspirated. If turbid fluid is evacuated the joint cavity should be emptied as far as possible. If the fluid is frankly purulent, the joint should be washed out with physiologic solution of sodium chloride. This is best done under a general anesthetic with two small lateral incisions. If the knee is involved, it is best to immobilize it in a plaster cast split up along the two sides, the anterior half may thus be removed easily for inspection. Aspiration informs one of the severity of the joint reaction, reveals the causative organism and mechanically relieves distention and pain. It can be repeated as required. In a fair proportion—possibly a majority—of cases, no other operative treatment is necessary, the arthritis subsides and, after a prolonged period of rest and immobilization, a useful, if not a complete, restoration of movement results. If aspiration or irrigation fails, there is no satisfactory alternative. Drainage is mechanically impossible, the insertion of tubes into joints always results in some degree of ankylosis. Drainage down to the joint has not met the success that was at first claimed for it.

Pneumococcal Meningitis—Waterfield states that the signs and symptoms may be vague or absent in meningitis, while in meningism they may be strongly marked. No definite points distinguish them except perhaps the tendency to hyperpyrexia in meningitis. Since meningism appears to arise invariably soon after the onset of pneumonia, one must always regard meningeal signs arising late in the disease as of the gravest significance. Meningism in adults must be extremely rare, hence meningeal symptoms in adult pneumonia suggests meningitis. Examination of the cerebrospinal fluid is the only means of making an absolute decision. In the past, recoveries seem to have occurred rarely irrespective of the treatment adopted. The introduction of Felton's serum has resulted in a larger number of cures. When available it should be employed, especially if the organism has been typed and found to belong to groups I or II. In eight of the author's cases of meningism, diagnostic lumbar puncture appeared to result in a dramatic improvement in the meningeal symptoms. But fatal results in such cases have been reported, and in one of his cases death followed rapidly from the formation of a pressure cone. When a lumbar puncture is performed the fluid must be removed slowly and in small amounts.

Secretion of Mucus by Stomach—Burger and his associates made quantitative estimations of the amount of mucus in the fasting contents of the stomach, in the basal secretion and in the juice obtained by stimulation with histamine and with physostigmine. Under these conditions the total amount of mucus and mucoprotein obtained from the stomach in simple achlorhydric anemia and in pernicious anemia is less than in health. The viscosity and high protein concentration of the gastric juice in simple achlorhydric anemia and in pernicious anemia are due to the decreased volume of secretion and the consequent inspissation of the juice. It is possible that the diminution of gastric secretion in these diseases is due in part to a coating of insoluble mucus on the surface of the stomach, which is too tenacious to be aspirated and which mechanically blocks the channels of gastric secretion. In view of the permanence of the achlorhydria the authors feel that this hypothesis is unlikely and that it is more probable that the gastric lesion is of an atrophic type.

Mode of Action of Quinine in Malaria—From supra vital studies of the blood of forty-six monkeys infected with Plasmodium mui (?) Krishnan found the mode of action of quinine to be as follows: 1. By accelerating the natural immune processes of mobilization, proliferation and functional activation of the phagocytic large mononuclear cells composing the reticulo-endothelial system the drug causes rapid engulfment and effective destruction of the malarial parasites. 2. By bringing about an alteration in the electrical condition of the parasites

and the infected red cells by direct action it increases the susceptibility of these to phagocytosis. 3 By slowing down asexual reproduction and occasionally leading to the formation of sexual forms, it checks the intensity of infection. 4 By indirectly leading to the production of humoral changes (antibodies) and to the sensitization of the cells of the reticulo-endothelial system it increases the resistance to reinfection. 5 By causing the removal of effete and old red cells and increasing the output of young red cells it renders the successful entry of parasites into these cells more difficult.

Antirachitic Activity of a Crystalline Compound—

Spence treated twelve actively rachitic children with daily doses of a crystalline compound derived from viosterol (calciferol) for eleven weeks or more. The therapeutic effects were estimated by serial roentgenograms, compared with a standard scale of the optimal rate of cure. A control of eight rachitic children was used to determine what spontaneous or automatic healing might have occurred had no vitamin D compound been given. The results showed that the compound had an active curative effect on the rickets and that it produced healing at an optimal rate, acting as quickly and effectively as the usual therapeutic doses of cod liver oil or viosterol. The results of the antirachitic activity of the compound were confirmed by observations on two pairs of twins, one member of each being kept as control and also on a child with an exactly controlled diet. In four cases 1 cc of the compound solution daily produced a maximal curative effect.

Thrombophlebitis in Acute Rheumatism—Perry reports three cases of venous thrombosis occurring during the course of acute articular rheumatism in childhood and presents a

review of other recorded cases. From the clinical features and histologic observations he concludes that a rheumatic phlebitis may occur as a rare feature of acute rheumatism. The venous thrombosis encountered in cases of acute rheumatism is secondary to the rheumatic phlebitis. There is nothing strange in the possibility of the rheumatic virus directly attacking the wall of the vein in view of the well recognized widespread character of the manifestations of the disease—arthritis, carditis, chorea, nodules—particularly since the characteristic histologic picture of the disease has been described in such situations as the arteries, the lungs, the pharynx and the diaphragm. Shaw described a cellular infiltration of the adventitia of the superior vena cava with swelling of the nutrient vessels in the case that he reported. The fact, noticed by many observers, that pain often precedes the swelling of the limb may be regarded as further evidence of a primary phlebitis antecedent to the secondary thrombosis. The rapid subsidence of the swelling that occurred in one of the author's cases has been noted by other observers. Whether it is due to venous occlusion being incomplete in the first instance, as suggested by Remlinger, or whether it is to be attributed to the development of an efficient collateral venous return is impossible to say. A further possibility is that much of the edema is caused by the involvement of the lymph nodes in the inflammatory process and that, with the subsidence of the acute inflammation, the lymphatic drainage once more becomes able to remove the greater part of the edema. Involvement of the lymph nodes may be the reason why in some cases the edema does not develop until some time after the onset of the pain.

Vaccine in Treatment of Cerebrospinal Fever—From his observation of more than 200 cases, Gayid considers that meningococcus vaccine should have its place in the treatment of cerebrospinal fever. It is indicated in (1) subacute and chronic cases, (2) inflammatory complications—e.g., arthritis and pleurisy, and (3) cases that are not affected by ordinary treatment. It is relatively indicated in (1) acute cases that become worse in spite of ordinary treatment although the disease in most of these cases is fatal, and (2) nervous and eye complications. In fulminating and hyperacute cases the vaccine has no effect in the first stage of the illness, and the best method of treatment in these cases is the repetition of lumbar puncture and the administration of serum intrathecally and intravenously with dextrose solution (40 cc of antimeningococcus serum and 250 cc of solution of dextrose), to be repeated every twelve or twenty-four hours. Simultaneously epinephrine should be injected subcutaneously to guard against any anaphylactic tendency.

Trauma and Epithelioma—Moran states that there is no experimental evidence that an epithelioma can be produced at will in a healthy subject by a single act of trauma. A single injury is capable of being a determining factor in the causation of epithelioma when applied to a precancerous lesion. An injury to an epithelioma may increase the rate of growth and the rapidity of generalization. Violence to a part in a subject suffering from a generalizing epithelioma may determine a local metastasis. Although the factor of coincidence must be of importance one is not justified from the present knowledge in denying the likelihood of causal relationship between trauma and epithelioma provided in the circumstantial evidence brought forward certain postulates are satisfied.

New Type of Degeneration—In two children de Lange observed a type of multiple degeneration of which she finds no description in the literature and which she designates typhus amstelodamensis. This type of degeneration is characterized by mental deficiency, a small underdeveloped body (birth at term with inferior weight which remains well below the average), brachycephaly, hypertrophy of the eyelashes and eyebrows, small hands and feet, abnormally proximal position of the thumb and thenar eminence, low placed ears and syndactylia of the toes. Other characteristics, which the author thinks may be accidental, are hirsutism of the forehead, an ogival palatine arch and curving inward of the little finger toward the ring finger. The syndactylia does not always affect the same toes. The two patients in whom this type of degeneration was observed were not related, and no similar dystrophies were found in their families. The author thinks that in these two cases it is probably a question of genotypic anomalies due to a lesion of the germ plasma, although one cannot completely rule out parakinetic factors.

Subcutaneous Asphyxiating Emphysema—Bourgeois states that the rare but grave occurrence of asphyxiating subcutaneous emphysema is practically always the result of a pulmonary perforation through a pleural adhesion during the attempted production of a pneumothorax. Severe emphysema does not result from the mere perforation of the lung but occurs if the fistula produced by the trocar remains permeable to air, which may happen if the instrument used is too large and, above all, if the tissues have lost their elasticity through infiltration and sclerosis of the lung and thickening and adhesion of the pleura. Asphyxiating emphysema may also occur at the end of a pleuroscopy, whether followed by the division adhesions or not. The progressive infiltration of the subpleural and subcutaneous tissue results from the extreme elevation of pressure produced by violent and repeated attacks of coughing. The average period between the perforation and the manifestation of the emphysema is five hours. In cases of asphyxiating emphysema the gaseous infiltration, once it is apparent, spreads with alarming rapidity, affecting first the neck and the eyelids, then the face, the shoulders and upper part of the arms (first on the side of the puncture and then on the other side). At the base of the thorax the emphysema is arrested for a time, the infiltration of the abdominal wall appears later and is more discrete. The emphysema gives rise to crepitation wherever it appears. The evolution of the emphysema is accompanied by progressive cyanosis and dyspnea increasing until death by asphyxiation occurs, usually within two or three days unless effective intervention is employed. The ideal intervention consists in closing the fistula. Ecot accomplished this in a case of fistula produced by a pleuroscopy by suturing the parietal pleura, the intercostal muscles and the pectoralis major. In the author's case, it being impossible to locate exactly the fistula caused by a small trocar, the intervention merely aimed at establishing a ready communication between the fistula and the exterior. This was done by means of a large crucial incision at the level of the puncture, systematic incision of the various layers to uncover extensively the intercostal region traversed, and tamponade of the wound to allow the free passage of gas. This deep incision resulted in the disappearance of the gaseous infiltration in less than forty-eight hours while multiple incisions of the skin for discharge of the air had only uselessly prolonged the duration of the emphysema.

10 1959 1998 (Dec. 11) 1933 Practical Section

- *Observations in Streptococcal Bacteriuria Particularly in Disease Groups
 Traceable to Local Infections F. Corelli—p. 1960
 Chundular Fever G. Lazzaro—p. 1964
 Idemitous Pancreatitis F. Truzzi—p. 1967
 Sudoral Disturbances in Diencephalic-Hypophyseal Syndromes A.
 Salmon—p. 1970

Streptococcal Bacteriuria in Focal Infections—Corelli studied the urine of 114 patients, divided into the following groups: (1) patients presenting no focal lesions and free from any disease associated with focal infections, (2) patients who, although apparently in perfect health, showed chronic tonsillitis, rheumatic pyorrhea or dental caries, and (3) patients having diseases associated with focal infections. In the second and third groups, seventy-one out of seventy-eight patients showed streptococci in the urine, the other seven showed isolated cocci, diplococci and various bacilli. In the first group of thirty-six patients the urine of thirteen was sterile, while that of twenty-three occasionally contained streptococci or produced mixed cultures. This indicates a relation between the presence of inflammatory foci, accompanied or not by general diseases, and the bacillary content of the urine. This relation becomes more apparent through isolation of anaerobic micro-organisms in the urine. The streptococci are more frequently anaerobic. If the urine of normal persons without foci and without preceding tonsillitis occasionally contains streptococci, there are only a few colonies. The carriers of foci, with or without associated diseases, present large amounts of streptococci. The urine of women affected with nephrosis contained from 500 to 1,000 colonies of streptococci in each 50 cc. tube of urine. The urine of a young patient having exophthalmic goiter, stomatitis and pharyngitis contained 1,000 colonies. Two patients with erythema nodosum showed from 800 to 4,000 colonies not only during the disease but three months after complete disappearance of symptoms. In three cases of acute articular rheumatism there was a greater number of diplostreptococcus colonies after termination of the febrile stage than at the beginning of the articular manifestations, while in cases of chronic ankylosing arthritis the number of colonies remained without notable variations but was always elevated. One case of recurrent chronic tonsillitis, which in the last attack was associated with a mild renal reaction, showed after tonsillectomy a pronounced increase of streptococci in the urine (2,000 colonies of hemolytic streptococci on blood agar), which rapidly diminished, completely disappearing on the tenth day after operation. The author maintains that bacteriuria may occur without a renal lesion in acute simple tonsillitis or in other diseases accompanied by tonsillitis. The relation between bacteriuria of tonsillitis (therefore bacteremia) and nephropathies should not be underestimated. Bacteriologic examination of urine in disease reveals the importance of localized chronic and acute inflammatory foci as the source of mild temporary bacteremias difficult to demonstrate and of streptococcal bacteriuria, and as points of origin of various modes of infection originating in a distant focus.

Report Rectified Concerning New Serologic Variety of Shigella Dysenteriae—De Assis rectifies his statement published in the *Brasil-Medico* 36 653 (Sept. 9) 1933 and abstracted in *THE JOURNAL*, Nov. 25, 1933, page 1763, on the behavior of a bacillus isolated from the feces of a patient suffering from acute febrile dysentery. The reactions of the bacillus to the glucides (sucrose, galactose, rhamnose, sorbitol, adonitol and glycerin) and especially its serologic reactions, were quite different from those given by a Hawkins strain, the latter being considered a classic example of the *Shigella ambigua* type. The new strain was considered as a new species of the *Shigella ambigua* group and was named the "Caxambu" variety. However, new cultural, biochemical and serologic studies of the Caxambu variety compared with seventeen different samples of the *Shigella ambigua* type proved that, con-

trary to the author's former statement, the variety "Craambu" agrees in all respects with the typical strains of the *Shigella ambigua* type. The Hawkins strain used as a control in the original study is the one that gave both cultural and serologic reactions entirely different from those given by typical bacilli of the *Shigella ambigua* group. Therefore the Hawkins organism is the new species of *Shigella ambigua*.

Sodium Fluoride Therapy in Hyperthyroidism—Goldenberg states that in patients having exophthalmic goiter or hyperthyroidism with increased basal metabolism and accelerated sedimentation speed the intravenous injections of sodium fluoride, administered for a long period varying from eight to twelve months (with some intervals of rest), retard the sedimentation speed until it becomes normal and also normalizes the basal metabolism thus producing complete recovery of the patient. In some cases the sedimentation speed becomes normal before the basal metabolism, which remains high for some time during the treatment, to become normal at the end of it. The results of the treatment in five cases are reported.

The Jadassohn-Bloch Skin Test—Steiner shows that the reliability of the Jadassohn-Bloch skin test with gauze dipped into a solution of the suspected substance has not yet been established beyond a doubt. In order to determine whether this skin test is capable of indicating an allergy in the organism or the skin, he made tests on 100 patients suffering from tuberculosis. Studies of these patients gave two possibilities for the solution of the problem: the comparison of the reaction with that in normal persons, on the one hand, and with tuberculin allergy on the other. The author's observations indicate that patients having tuberculosis react to dilute solutions of corrosive mercuric chloride more frequently than do healthy persons; that is, the stimulation threshold of tuberculous patients is much lower than that of normal persons. The intensity of the reactions likewise indicated the greater susceptibility of tuberculous patients, for they gave stronger reactions in a larger percentage of cases. The author observed that there is a certain parallelism between the outcome of the tuberculin test and the Jadassohn-Bloch allergy test. He thinks that this parallelism can be due only to a factor that is involved in both tests: the vasomotor reaction and he concludes that the Jadassohn-Bloch skin test with saturated gauze is largely dependent on the vasomotor reaction but he questions the value of the test for the detection of specific allergic conditions.

Serologic Tests of Cure in Gonorrhea—Dorffel describes studies which corroborated his opinion that the complement fixation test may remain positive for months and even for years after the clinical cure. Thus its positive result does not necessarily indicate the existence of a latent focus, but its persistence may be taken as a warning. If the antibody titer is determined with successively decreasing quantities of serum, the complement fixation reaction permits a more exact estimation of the acuity of the gonorrheal process. If the gradual decrease in the quantity of antibodies corresponds with the clinical aspects, it may be accepted that, as a result of the decrease in the growth of gonococci and of their gradual disappearance, gonococcus toxins are no longer absorbed by the urogenital system, and that the formation of antibodies likewise ceases. The gradual decrease in the antibody titer is thus an indication for an approaching or accomplished cure. A renewed increase, however, indicates an exacerbation (complication) or a relapse. Protracted cases of gonorrhea with complement fixation reactions that are either negative or become only weakly positive (up to 1:10) generally have a poor healing tendency and consequently an unfavorable prognosis. The same applies to complicated cases with negative or weakly positive reaction. Tests with antigonorrheal vaccine on normal persons indicated that a positive reaction may persist for a number of months, in spite of the fact that gonococcus toxins are no longer administered. On the basis of these studies the author recommends that in difficult cases, particularly in the granting of marriage licenses and in forensic matters, the complement fixation reaction be made with successively decreasing quantities of serum, since the curve outlining the results of several tests permits conclusions about the course the process is taking.

Hypersusceptibility to Arsphenamine—Vuletic describes a form of hypersensitivity to arsphenamine not reported heretofore. It developed in the author and his assistant as the result of daily contact of the fingers with arsphenamine solutions and from inhalation of the solutions, when they administered anti-syphilitic treatment to great numbers of patients in Bosnia. Neither he nor his assistant had taken arsphenamine in any form. The disturbance became manifest at first as a mild dermatitis of the fingers, but later deep fissures and deep structural changes of the skin developed. Typical attacks of asthma occurred only at one of the stations at which they worked, and it was found that the air of the room in which they worked contained dust in addition to the arsphenamine vapors, for the ventilation was insufficient. The assistant developed in this epicutaneous manner a universal arsphenamine urticaria, Quincke's edema and acute arsphenamine poisoning. The symptoms of the latter resembled those of acute arsenic intoxication (vomiting, headaches, pains in the extremities, mucosanguineous diarrheas, thready pulse, fever, and albuminuria). The finger dermatitis of the assistant was refractory to all therapeutic measures, and it still exists, two years after its first appearance. Skin tests with the application of gauze saturated with arsphenamine were positive, while tests with solution of potassium arsenite were negative. If these reactions permit definite conclusions, the hypersusceptibility and intoxication must be considered as the action of the unchanged arsenobenzene molecule.

Status of Serum Treatment of Gas Edema—Lohr states that anaerobic serums in their present form do not guarantee absolute protection against the development of gas

edema, but he rejects the statements of certain authors that the serums are altogether useless. He recommends the immediate administration of large doses of serum to patients who have sustained serious injuries, especially those in whom the wound cannot be excised. The author treated seven patients with anaerobic serum. The serum was administered as a means of immunization but failed to retard the edema. Continued administration of the serum after edema had developed however, resulted in a favorable number of cures. The author states that, in the event of gas gangrene large doses of serum should be administered along with surgical measures or even eventual amputation. He believes that scrothotherapy should not be regarded as useless and superficial but as valuable in the presence of ever increasing automobile accidents and the possibility of war. The great frequency and toxicity of the Welch-Fraenkel bacillus (*Bacillus perfringens*) warrants more consideration in bacterial research. In cases of severe destruction of tissue it is advisable to administer large doses on account of the rate of toxin formation and the type of growth of the gas bacillus. In manifest gas edema anaerobic serum should be given in large quantities for curative purposes. According to observations made by the author during the war and in peace times, this serum has in many cases mitigated the otherwise malignant course of gas edema and has considerably reduced its mortality rate.

*Vertebral Chordoma. O. Simon.—p. 805

Vertebral Chordoma.—Of the three types of chordoma the cranial the caudal and the vertebral the last mentioned is the rarest, according to Simon. Podlaha and Pavlica collected forty-four cases of cranial chondroma including their own up to 1928. The author reviews five cases of vertebral chondroma existing in the literature and adds one of his own. His patient a woman aged 57, complained of increasing difficulty in deglutition. At operation a tumor springing from the anterior surface of the cervical vertebrae and compressing and displacing the esophagus was found. The tumor was removed. Nine months later there was a recurrence in the scar with pressure on the brachial plexus. The patient would not consent to removal of the recurrence. The tumor was lobulated and possessed a capsule which sent septums into the interior. On histologic examination the tumor was found to be made up of two kinds of cells, small polygonal cells with homogeneous plasma and large physalis cells containing characteristically vacuolated plasma. The tumor lobules reproduced the structure of the notochord which likewise contains small epithelial cells in its peripheral sections and physalides in the median sections. The malignant character of the tumor cells manifested itself in the tendency to invade the capsule the connective tissue septums and the capillaries. Formation of metastases was reported in only eight of the forty-four cases. On the other hand local recurrence after operative removal was the rule. All chordomas, vertebral as well as those of the sacro coccygeal region are to be considered malignant. The intimate relationship between the tumor and the bone from which it develops makes it difficult to remove it completely and favors the recurrence of the tumor. Vertebral chordoma originates from the remains of the notochord within the vertebral body. Two distinct types may be distinguished the intravertebral and the antevertebral. The intravertebral chordoma grows in the direction of the spinal canal and causes symptoms of transverse paralysis. The earliest symptoms of the antevertebral variety are those of pressure displacement of neighboring organs with involvement of peripheral nerves. Prognosis is bad in both forms because of inability to remove the tumor completely. It may be possible to obtain better results in the future by irradiation.

Is Vitamin B the Active External Factor in Pernicious Anemia?—Diehl and Kühnau call attention to the studies of Castle and Strauss which were reported in the *Lancet* (2 111 [July 16] 1932 abstr. THE JOURNAL Oct. 8 1932 p. 1300), and which gave evidence that a substance which is closely related to vitamin B or is vitamin B itself, is the extrinsic active factor in pernicious anemia. In order to determine whether the extrinsic factor really is vitamin B the authors treated three patients who had pernicious anemia with a purified B preparation that had been exposed to the influence of gastric juice. They observed an increase in reticulocytes on the fourth or fifth day, but this increase was not as large as is normally the case. The thrombocytes likewise increased slightly, but the hemoglobin and the erythrocytes either remained unchanged or decreased. Under the influence of the B alone not even the slight increase in reticulocytes was noticeable. In view of the fact that the authors used a rather concentrated B extract and that consequently the quantities of vitamin received by their patients were if anything even larger than those given by Castle and Strauss they reach the conclusion that vitamin B cannot be the extrinsic factor referred to by these investigators. But since the latter found fresh yeast effective the authors think that some other substance contained in yeast but not vitamin B must be the active extrinsic factor.

Thallium Poisoning.—Ludwig and Ganner describe three cases of acute thallium poisoning. The patients at first did not admit having ingested thallium and the disturbances were not correctly diagnosed until the characteristic loss of hair set in. The initial symptoms are paresthesia and severe pain in the extremities, particularly the legs. Intestinal disturbances of a colic-like character may develop within the first forty-eight hours but as a rule they do not become manifest until several days later. Renal disturbances in the form of albuminuria and cylindruria occur generally during the first week. The cardiac disorders that present themselves within the first two weeks are tachycardia, weak pulse and, occasionally, stenocardial symptoms. Acute dilatation and collapse may threaten. Insomnia appears early and is much complained of. It may be partly caused by the severe pains, but as a rule it persists after the pains have disappeared and consequently the intoxication as such must play a part. Disturbances of the bladder in the form of inhibition of micturition or of incontinence exist for a number of weeks and the incontinence of the bladder may be accompanied by that of the bowel. The pathognomonic loss of hair generally sets in during the third week following the ingestion of the poison. The authors also noted changes in the nails (white streaks) and, in one case cutaneous changes in the nail bed. They think that the initial paresthesias and pains in the extremities were a manifestation of polyneuritis, which in two cases later developed into a degenerative atrophic paralysis. Involvement of some of the cerebral nerves (facial and recurrent), although rare in thallium poisoning, has been observed in two cases. The functional disturbances of the bladder were probably caused by an impairment of spinal nerves. Whether the temporary ataxia, which in one patient involved all the extremities and the trunk, was of central or neuritic origin could not be determined. Metabolic tests revealed abolishment or reduction of the specific dynamic protein action.

Clinical Aspects of Adams-Stokes' Disease—Milew describes the clinical and electrocardiographic aspects of two cases with complete block. In one of the patients there existed in the beginning most likely sinus block and complete auriculo-ventricular dissociation, during which the ventricles probably worked under the rhythm of the right bundle branch. In the other patients there existed only a ventricular automatism. After a number of years the first patient developed a retrograde conduction from the ventricles to the auricles. In the second patient it was proved by anatomopathologic studies that the sclerotic changes of the vascular system of the heart particularly the complete obstruction of a branch of the right coronary artery, were the cause of the complete block. Electrocardiography revealed that in the first patient the inhibition of myocardial nitrite deepened the P wave of the transferred auricular contractions.

Reduction of Serum Lipase by Thyroxine—Bruer and Hoffman direct attention to the observations of several Hungarian investigators, who noted that a single subcutaneous injection of thyroxine effects in rabbits a considerable reduction in the lipase content. They point out that their own observations of the extremely low lipase values in patients with exophthalmic goiter correspond to this thyroxine effect, and that the thyroxine test is a simple method for the demonstration of substances that protect against thyroid intoxication. After reviewing some of the contradictory reports about these substances, they call attention to the studies of Anselmino and F Hoffmann, who succeeded in isolating from the blood and tissues of normal animals a lipid substance that protects against thyroxine. They relate their own investigations on these problems in rabbits. They were able to confirm that the subcutaneous injection of thyroxine (from 0.25 to 0.5 mg) causes a considerable reduction in the serum lipase which far exceeds the spontaneous fluctuations. By means of the lipid extract that Anselmino and Hoffmann isolated from the blood they inhibited the effect of thyroxine on the lipase content. Small amounts of the lipid substance dissolved in oil were fed to the animals for seven successive days. Then they were given injections of 0.25 mg of thyroxine for a number of days and these injections did not reduce the lipase content. Later 0.5 mg of thyroxine was administered at irregular intervals but even these amounts did not reduce the lipase as late as thirty eight days after the feeding with the protective substance. In two animals the protective action of ordinary olive oil was tested and it was observed that olive oil has a certain protective value but that it is far inferior to the lipid substance. Other tests revealed that thyroxine reduces not only the lipase but also the fat content.

Rôle of Reticulo-Endothelial System in Reduction of Serum Lipase by Thyroxine—In view of the protective action of fats and lipoids against thyroxine Dell Acqua and Strauss decided to determine whether the reticulo-endothelial system plays a part in this protective action. For this purpose they blocked the reticulo-endothelial system of rabbits with trypan blue and then determined whether this blockage as such

influences the lipase content of the blood serum or whether the blockage inhibits or changes in any way the lipase reduction produced by thyroxine. It was found that in none of the animals did the lipase content of the serum change either during or after the blockage of the reticulo-endothelial system, at least there was no change in excess of the spontaneous variations. Two animals were given an injection of 0.5 mg of thyroxine nine days after the last injection of trypan blue. The thyroxine injection was followed by the typical reduction in the lipase, which, if anything, was even more intense than is the case ordinarily. These observations indicate that a blockage of the reticulo-endothelial system with trypan blue does not protect against thyroxine.

Influence of Splenic Substances on Cholesterol of Blood—Schliephake calls attention to studies in which he succeeded in isolating an active substance of the spleen. This substance influences the metabolism as well as the immunobiologic processes in the organism. The influence of the splenic hormone on metabolism manifests itself in various functions, and in former studies the author has investigated its influence on the circulation. He found that the circulatory changes produced by the spleen do not become manifest in direct vascular reactions such as dilatation or constriction but are of a purely potential nature in that they change only the reaction capacity. On the basis of the assumption that these processes are the result of changes in the humoral composition of blood and tissues the author examined various constituents of the blood and their modification by the spleen. He studied the relations of the spleen to the defense mechanism of the organism and found that the splenic hormone activates the reticulo-endothelial system and increases the phagocytosis of the leukocytes. In the course of these investigations his attention was drawn to a substance that plays a part in the circulatory system as well as in the defense mechanism namely cholesterol. He observed that the cholesterol content of the blood is changed by the splenic hormone. The change is usually an increase and is the more pronounced the lower the initial value. In case of high initial values the increase may be followed by a decrease. In order to control his observations the author resorted to irradiation of the spleen with ultrashort waves and found that this procedure is likewise followed by changes in the cholesterol content. The intravenous injection of the splenic hormone is always followed by an initial increase, while in case of intramuscular injection or of irradiation with ultrashort waves the increase may be preceded by a decrease which never lasts longer than an hour.

Serodiagnosis of Syphilis on Cadavers—In order to determine the serologic method best suited for the diagnosis of syphilis on cadavers, Knepper compared the results of the Memmcke turbidity reaction in the pericardial fluid, of the Wassermann reaction in the native serum and of the so-called corroboration reaction devised by Witebsky. The latter reaction consists of a separation of the union of antigen and antibody for by an increase in temperature the antibodies can be separated again from the antigens to which they are united. If a flocculation has taken place the specific union of which is doubtful, an attempt may be made to separate the antigen-antibody compound and then to demonstrate the antibodies again. However before attempting the separation of the antigen-antibody union in a flocculate it is necessary to free the sediment from serum containing intermediate fluid and from the nonspecific serum albumins and serum globulins by repeated washings with cold sodium chloride solution. After sufficient washings, the separation fluid contains only slight traces of serum protein. Since the nonspecific seroreactions are dependent on the presence of relatively large amounts of serum protein such a reaction is impossible in the separation fluid. Witebsky employs for the flocculation the older technic of the citochol reaction. The author gives a description of the technic and a tabular report of the results obtained with the three tests on 500 cadavers. His results indicate that the Memmcke turbidity reaction on the pericardial fluid is least subject to nonspecific reactions and to auto-inhibitions, however in many cases of syphilis it remains negative because of the insufficient antibody content of the pericardial fluid. The Wassermann reaction of the native cadaver serum is unsuitable because of the great tendency to nonspecific reactions and auto-

inhibitions (particularly during the summer time), although it indicates a considerable number of the actual cases of syphilis correctly. Witebsky's corroborative reaction together with the Wassermann reaction gives good results on cadavers and the author recommends this procedure, for it is the only one that has given satisfactory results in cases in which the clinical and anatomic diagnosis was not quite clear.

Isolation of Estrual Hormone and New Phenomenon—Masao Ito and Seiji Hayazu describe a simple method for the isolation of the estrual hormone in crystalline form, which they employed on the urines of pregnant horses and of women. After the urine has been acidified with hydrochloric acid, it is filtered through diatomaceous earth. Animal charcoal is added to the filtrate in order to absorb the hormone. After thirty minutes of boiling the suction filter is used, and the remaining charcoal is washed with dilute solution of alkali until the fluid becomes clear. Following rinsing with alcohol, the charcoal is extracted by being heated two or three times with phenol. The extraction medium is removed by distillation and the hormone-containing residue is dissolved in diluted alcohol and boiled with ten times its quantity of benzene. After cooling, the benzene is removed and these procedures are repeated several times. The hormone-containing, yellow benzene particles are mixed with a 2 per cent solution of sodium carbonate and washed until the fluid becomes clear. The discolored benzene solution is concentrated and repeatedly shaken with a 4 per cent solution of sodium hydroxide. From 90 to 95 per cent of the active substance enters the soda solution, which is then neutralized with hydrochloric acid. The sediment is saponified by dilution in a 5 per cent solution of sodium hydroxide and boiling for one hour. After cooling, it is repeatedly shaken with ether, so as to make the hormone pass into the ether, and, after evaporation of the ether, yellow crystals precipitate, but after being washed with ether they become colorless. The remaining oily substance is again saponified and treated with ether, and by repetition of this procedure several times 60 per cent of the hormone can be crystallized, while the remaining 40 per cent remains in the oily substance. The authors report that they stored pregnant urine, which had been acidified with acetic acid and then evaporated, so that a thick extract remained. The hormone content of this extract was determined from time to time, and after one year the hormone content increased unexpectedly almost nine times, while other extracts, which had been prepared with alcohol and acetone, revealed no change in the hormone content. The authors advance as the most likely cause of this phenomenon the fact that the extract probably contains a prehormone, which, by a still unidentified factor, is changed into the hormone.

Diastase in Urine in Necrosis of Pancreas—Rost shows that acute necrosis of the pancreas may take an atypical course and that in these cases the diagnosis is extremely difficult. He has observed cases that exhibited all signs of poisoning or of cardiac disturbance. In one patient the cardiac symptoms were so severe that in spite of the intense pains in the left epigastrium the operation was dispensed with and the patient recovered. The diastase reaction according to Wohlgemuth-Baumann was made repeatedly in this case but always gave normal values.

This normal diastase content of the urine in a patient who had the signs of an acute pancreatic necrosis induced the author to investigate the reports on the diastase values in cases of necrosis of the pancreas. In the course of these investigations, Baumann called his attention to the fact that the original method of Wohlgemuth gives unreliable results, because buffering of the urine, which is an essential requirement, had been omitted. In further tests, he saw to it that buffering was done, and he reaches the conclusion that the diastase determination in the buffered urine is a reliable aid in the diagnosis, although there is a possibility that low values may occur in cases of necrosis of the pancreas, for no clinician will expect a 100 per cent reliability from a single method. Recently he found the diastase determination helpful in two cases in which the differentiation between perforation of the stomach and necrosis of the pancreas offered difficulties. The method is helpful also in cases of gallstone, for it indicates pancreatic involvement and it shows in how many of these pancreatides recovery takes place without an operative intervention. The author stresses the necessity of individualization in deciding on an operation in pancreatic impairments. However, he does not advise against surgical treatment in general. In cases in which the attacks of pain persist or recur in short intervals, the operation should not be postponed. Only in cases in which the cardiac symptoms predominate and the abdominal symptoms show a tendency to subside is an expectant attitude advisable.

Fate of Patients with Eclampsia—Schultz shows that a transition of eclampsia or of the renal disorders of pregnancy into chronic nephritis is extremely rare. Of 239 cases that were carefully controlled only one such case was observed. In this instance there were no indications that a renal disturbance had existed before pregnancy, but, of course, this does not necessarily prove that it developed during pregnancy. The author admits that an existing chronic nephritis may be exacerbated and that under the influence of an eclampsia and a renal disturbance of pregnancy with hypertension it is possible that a sclerosis of the vessels and with this a nephrosclerosis may develop or become exacerbated.

Treatment of Furuncles—Winckler treats furuncles and carbuncles, particularly those of the face, with the Paquelin cautery. He emphasizes that the cautery must be at white heat, for only thus will it be possible to introduce it without special pressure and without severe pain deep into the infectious focus. It is also essential to introduce the cautery vertically into the center of the focus, so as to destroy the necrotic cone. In small furuncles a single application of the cautery is sufficient, provided it is deep enough. However, if pus exudes, the cautery is introduced once or twice more until pus no longer comes up. Experience on himself convinced the author that the method is not unduly painful. Following cauterization, a dry sterile bandage is applied.

Gonorrheal Endocarditis of Pulmonary Valves—Ziegler discusses the etiology and the symptomatology of endocarditis of the pulmonary valves. Statistics reveal that the primary lesions of the pulmonary valves are most frequently caused by the gonococcus and the pneumococcus, the gonococcus being about twice more frequent than the pneumococcus. The author cites eleven cases of gonorrheal endocarditis of the pul-

monary valves from the literature and then reports three cases observed by him. One case did not end fatally, but its etiology, clinical and roentgenologic aspects indicated a gonorrheal endocarditis of the pulmonary valves. The other two patients died of gonococcal sepsis. In the first case the pulmonary valves were not involved, while in the second only the pulmonary valves were affected. The second case is reported in detail. The diagnosis of insufficiency of the pulmonary valves was based on the diastolic murmur that is loudest over the pulmonary valve, on the eventually existing hypertrophy of the right ventricle with epigastric pulsation and on the sharply projecting arch of the pulmonary valve as well as on the brisk pulsation of the pulmonary artery visible during roentgenoscopy.

Traumatic Cerebral Pneumatocoele—Muller points out that the accumulation of air in the cranium, which is occasionally observed following traumas of the head takes place most frequently in the space formed by the trauma. Next in frequency as the site of these cerebral pneumatocoeles is the ventricular system of the brain. The extracerebral localization, between the surface of the brain and the dura mater, is comparatively rare, but the author observed such a case and describes it in detail. The case report is followed by a discussion of the general aspects of cerebral pneumatocoeles. Traffic accidents resulting in fractures of the frontal bone, the ethmoid bone, the sphenoid bone or the mastoid process are generally the cause. In many cases the accumulation of air does not develop until several days, weeks or even months after the accident. The eliciting cause is frequently an increase in pressure in the pneumatic spaces produced by sneezing, blowing of the nose, coughing, swallowing or physical exertion. The symptoms vary according to the quantity of air and the resulting pressure and according to the localization and the simultaneous injury of the brain tissue. Thus it is possible that neurologic symptoms are entirely absent or there may be disturbances varying in degree to the severest symptoms of irritation, abolition of function and pressure. A peculiar splashing sound, when the head is moved is observed in comparatively rare cases, but, if present it has pathognomonic significance. Differences in percussion sound are occasionally perceptible such as tympanism on the side of the air accumulation. A periodic discharge of fluid (generally from the nose) frequently influenced by body posture makes the presence of a cerebral pneumatocoele highly probable. The definite proof must be given by roentgenoscopy. When spaces contain both fluid and air a fluid level may become evident in the roentgenogram. Whenever in the course of convalescence following cranial trauma severe headaches recur, roentgenoscopy should be repeated. The treatment must be decided in each case. Rest in bed and immobilization of the head is sufficient in many instances. In other cases operative interventions may be necessary such as puncture trepanation or repair of dural tears. The eventually existing fluid fistula may be treated with roentgen rays. For the prophylaxis of the accumulation of air it is important that patients whose pneumatic spaces have become exposed by a cranial trauma refrain from blowing the nose, suppress sneezing and coughing and avoid exertion (abdominal pressure).

Cubital Patella—Ewald reports the clinical history of a man aged 28, who had been a boxer and wrestler for several years until he developed pains on the extensor side of the elbows and repeated exudates into these joints. At first these symptoms disappeared when he discontinued his strenuous exercise but later they even appeared during work. Examination of the muscular arms that never had been injured revealed that the elbows were rather plump and that the olecranon did not project as sharply as is normally the case. Complete extension of the elbow proved impossible while flexion was not inhibited. A bone 5 cm in length and 3 cm in width could be palpated above the olecranon proper. This bone could not be separated from the triceps tendon but could be moved readily against the posterior articular surface of the humerus and against the olecranon. Roentgenoscopy revealed a bony structure opposite the humerus and the olecranon. The latter was covered as with a bowl but was not atrophied. The patient demanded removal of the bones. The author cites other cases of cubital patella from the literature and calls

attention to the theory of Kienbock who thinks that the cubital patella is generally the result of traumatic detachment during childhood of the epiphysis on the upper portion of the ulna. In view of the perfect development of the structures observed by him, the author rejects this theory of traumatic origin and thinks that the cubital patella just like that of the knee joint, is a true sesamoid bone, which, like the supernumerary bones in the carpus and tarsus, must have an embryonic origin.

Iron Therapy in Chronic Chloranemias—Reimann maintains that the chronic posthemorrhagic anemias, achylic chloranemias, many forms of postenteritic and postdysenteric anemias, anemias after deficient and unsuitable nutrition, some anemias that develop after febrile and toxic conditions, many of the so called agastric anemias and some cases of chloranemias of obscure origin belong to the same group and may be considered as a unitary hematologic disturbance. The two main characteristics of these anemias are a disturbance in the hemoglobin metabolism and a sensitivity to iron. The disorder in the hemoglobin metabolism is indicated by hemoglobin deficiency, hypochromia of the erythrocytes, low color index, microcytosis and absence of all signs of increased regeneration. There is a change in the bone marrow, namely, the "red erythroblastic marrow" and the contrast between its high cell content and its apparent content of hemoglobin on the one hand and the decrease of cells and of hemoglobin in the blood on the other hand. The cause of this phenomenon is that the erythroblasts, insufficiently provided with hemoglobin, are arrested in their development to normal erythrocytes. Medication with iron is followed by a rapid increase of the hemoglobin content, the number of erythrocytes and the color index, that is, the iron counteracts the disturbance in the hemoglobin supply and its sequels. The number of erythroblasts in the marrow becomes smaller, for since they receive a sufficient amount of hemoglobin they develop into normal erythrocytes and enter the blood stream. The point of attack of the iron is thus in the bone marrow. The action of iron is specific; it cannot be replaced by any other medicament and its efficacy is restricted to this group of anemias. Since there is no common term for these anemias, the author suggests the term "ferrosensitive chronic chloranemias," and since they are deficiency diseases (lack of iron) they may be designated also as "asideroses."

Action of Liver in Pernicious Anemia—Reimann and his associates show that there is a great difference between oral and parenteral liver therapy. The same dose of liver is much more effective in parenteral than in oral therapy, and, in order to produce the same effect on the blood, the oral dose must be from thirty to fifty times as large as the parenteral dose. The pathologic condition of the digestive tract in pernicious anemia exerts a detrimental influence on the utilization of the orally administered liver. The absence of gastric digestion and the rapid passage through the gastro-intestinal tract reduce the resorption of the active substance. Studies carried out by the authors indicated that the resorption of the active principle takes place primarily in the upper portions of the intestine. If liver is introduced directly into the intestine without passing through the stomach its efficacy is reduced in proportion to the lower level at which it is administered in the intestine. Careful observations on four patients disclosed that rectally administered liver and liver extracts have no

effect on the blood status, and consequently the authors reject rectal liver therapy as unreliable. Digestion experiments with trypsin and erepsin indicate that destruction of the active substance by the fermentative processes in the gastro-intestinal tract is not likely and that the active antianemic principle of the liver is not a polypeptide, and that therefore a polypeptide-like binding to another complex can be excluded. The authors inquire whether the superiority of parenteral liver therapy may not be due to the fact that in oral administration and the subsequent resorption in the gastro-intestinal tract a large portion of the active substance is intercepted by the liver stored there, and thus withdrawn from its utilization by the hematopoietic system. In parenteral administration the substance is offered directly to the blood producing organs and can therefore exert a more intense influence. The authors think that the great difference between the efficacy of the oral and parenteral administration is not the result of one but of several factors. Because these factors vary in different cases an exact determination of the oral dose is difficult.

Stimuli of Incretory Activity of Pancreas—De la Vega employed stimulatory and depressive substances, secretin and insulin, to test the pancreatic action. Her tests were made on white mice. She found that small quantities of insulin, given at short intervals effect a decrease in thecretory issue while larger amounts given at longer intervals have the opposite effect. Secretin always produces an increase in thecretory tissue of the pancreas. The author reports her observations on rabbits, the pancreas of which was irradiated with roentgen rays. She reaches the conclusion that the roentgen rays stimulate thecretory function of the pancreas. Anatomic studies on the pancreas of irradiated animals gave somewhat contradictory results, and she is as yet unable to say whether the increase in thecretory action of the pancreas is due to true hypertrophy or to hyperplasia of the islands of Langerhans.

Rôle of Stomach and Liver in Pernicious Anemia—Bence removed the stomach of hogs and found that these gastrectomized animals developed an anemia of hypochromic and microcytic character somewhat resembling achylic chloranemia. However the main purpose of this experiment was to use the liver of these animals for the preparation of a liver extract and then to try this extract on patients having pernicious anemia. It was found that the liver of gastrectomized hogs did not produce a noticeable increase in the number of erythrocytes. Moreover, the hemoglobin was hardly at all influenced the color index remained above one and megilocytes persisted. These observations indicate that, after resection of the stomach the liver loses its influence on anemias, and from this it can be deduced that the stomach is the site of formation of the liver substance that influences anemia. The liver either stores this substance or gives it its active form. The author shows that the substance active in blood formation does not originate from the disintegration products of foods. He thinks that the active stomach substance is a product of internal secretion.

Treatment of Urethral Gonorrhea in Women—In refractory cases Hofstätter obtained favorable results by injecting vaccine near the inflammatory foci, a method that had been recommended by his chief, Bucura. He employed this treatment successfully as far back as 1924. In the years following, his attention was drawn to the efforts of French authors, who first recommended vaccination at the port of entry but later made the injections at all sites where the gonococcus had caused manifestations of disease including the joints in which gonorrheal inflammations or suppurations had developed. It was found that this method was ineffective in acute cases and that it obtained results only when the gonococci were no longer on the surface but had entered the tissues. From 1927 to 1930 the author treated one group of gonorrheal infections with the

method recommended by the French authors and another group with Bucura's method. He found the latter method more effective. Following disinfection of the urethral opening with corrosive mercuric chloride, the urethra is anesthetized by a 20 per cent cocaine solution and from five to ten minutes later the vaccine injection is given. The para-urethral region, as a rule and sometimes also the urethra must be anesthetized by injecting a 1 per cent solution of tutocain. Since this local therapy is employed only in cases that have previously been treated with intramuscular vaccine injections, the initial dose may be relatively large as a rule 0.5 cc. Gradually the dose is increased to 2 cc. In order to obtain a better distribution, Bucura advises the dilution of the first doses with sodium chloride solution to make 2 cc. The para-urethral vaccinations are often accompanied by severe general reactions. For this reason it is important that during the first three or four injections the patients be kept in bed. It should be remembered that mixed infections exist in most para-urethral processes. One or two injections of a mixed vaccine follow the injections of gonococcus vaccine in the author's practice.

 *Rupture of Liver in the New-Born Observed at General Lying-In Hospital in Helsingfors from 1924 to 1932. Eva Holmberg—p. 1067

Quantitative Determination of Protein in Cerebrospinal Fluid—Salminen examined normal cerebrospinal fluid from forty-five patients and pathologic fluid from twenty-five by the aid of the xanthoprotein reaction and by the use of the Leikola-Noponen universal colorimeter. The procedure is easy, simple and quickly performed by any person not color blind and the results agree with those of other investigators. One hundred cubic centimeters of normal cerebrospinal fluid contained an average of 25 mg of total protein, 20.81 mg of albumin and 4.19 mg of globulin with a protein quotient of 0.23. In paralysis the total protein and its two fractions were greatly increased, the globulin relatively far more than the albumin and the protein quotient was often above 1. In locomotor ataxia the total protein and the globulin content were increased, the former considerably less than in paralysis, and the protein quotient seldom exceeded 1. In cerebral syphilis the protein relations corresponded approximately to those in locomotor ataxia.

Treatment of Epididymitis by Hemolyzed Blood—Ingman used this method in forty patients with gonorrheal complications. By control of the blood sedimentation reaction and careful dosage the negative phase was avoided. The results were satisfactory and apart from a temporary rise in temperature in some cases, there were no by-effects.

Rupture of Liver in the New-Born—Holmberg says that in a necropsy material of more than 1,000 fetuses observed in the General Lying-In Hospital in Helsingfors from 1924 to 1932 there were three cases of ruptured liver in full term fetuses, two of these after spontaneous delivery, seven in premature cases, and nine in fetuses weighing less than 1,000 Gm. Subcapsular liver hematoma was found in eleven full term and twenty-six premature fetuses. The rupture of the liver is believed to be due to trauma with asphyxia and presumably also a pathologic tendency to hemorrhage as disposing factors. The subcapsular liver hematomas are thought in the main to depend on similar causes.

SYPHILIS AND PREGNANCY

AN ANALYSIS OF THE OUTCOME OF PREGNANCY IN
RELATION TO TREATMENT IN 943 CASES

JOHN L. McKELVEY, MD
AND
THOMAS B. TURNER, MD
BALTIMORE

The presence of an untreated syphilitic infection in the pregnant woman greatly reduces the chance of the birth of a normal baby. As a result of the widespread application of serologic tests to the diagnosis of clinically unrecognizable syphilis and the almost universal use of arsphenamine or related products in the treatment of the disease, there has occurred a striking decrease in the incidence of fetal and infant mortality due to syphilis. The accumulated experience of many workers with the newer methods of treatment has made it evident that congenital syphilis is an almost entirely preventable disease and that one of the most fruitful fields of preventive medicine is open to the obstetrician. Although these main facts are well known, certain of the minutiae of treatment require more detailed elucidation.

In this paper the records of nearly 1,000 pregnancies occurring in syphilitic women are analyzed with regard to the effects of the disease on the product of conception and the results achieved by antisyphilitic treatment. The study has made it possible to offer definite statements as to certain controverted points, such as the relative value of the Wassermann reaction and placental histology, the optimal amount of arsphenamine to be administered during pregnancy, the efficacy of the heavy metals, and the value of preceding antisyphilitic treatment during subsequent pregnancies in which no treatment is given.

SOURCE OF MATERIAL AND METHOD OF STUDY

The basis for this study is afforded by an analysis of the outcome of 943 pregnancies in known syphilitic women delivered under the supervision of the obstetric department of the Johns Hopkins Hospital. All pregnancies occurred between the years 1914 and 1930, inclusive, a period corresponding roughly to that during which the arsphenamines have been generally employed in the treatment of syphilis. Pertinent data have been obtained through the departments of obstetrics, pathology, medicine (syphilis clinic), pediatrics and roentgenology. For each pregnancy, information on the following points has been assembled when available: result of syphilologic examination of the mother and

the kind and amount of antisyphilitic treatment received by her before or during pregnancy, duration of pregnancy at the start of treatment, condition of the child at birth, result of the Wassermann test on the blood of the umbilical cord, microscopic examination of the placenta, follow-up examination of the child in the pediatric clinic, roentgen examination of the baby for syphilitic epiphysitis, and the postmortem observations if the infant was still-born or died soon after birth.

The 943 pregnancies comprising the study occurred in 644 women, each of whom was infected with syphilis prior to delivery. Of these, 78 belonged to the white race and 566 to the Negro race, all were among the public ward class of patients. Each patient was submitted to much the same routine. On admission to the obstetric clinic a Wassermann test on the mother's blood was made, and, if found to be positive or if there was other evidence of the existence of maternal syphilis, the patient was referred to the syphilis clinic for further examination and antisyphilitic treatment when indicated. In many instances, patients presented themselves to the obstetric clinic for the first time during labor. Among this group were 117 women, accounting for 124 pregnancies, who did not reach the syphilis clinic before delivery. The duration of pregnancy at the start of treatment is expressed in terms of lunar months, ten lunar months being accepted as the normal period of gestation. The diagnosis of premature delivery is based on weight and length measurements of the child as outlined in Williams' "Obstetrics."¹ The definition of children born alive or born dead follows the usual criterion, in that infants who breathe are recorded as living.

Approximately three fourths of the children surviving the first weeks of extra-uterine life were later examined by the pediatricians for clinical and serologic evidences of syphilis. In the tabular presentation of our material the ultimate status of the child is recorded as normal or syphilitic, on the following basis:

A child is classed as normal only if it is born alive and found on subsequent pediatric examination (usually including routine roentgen examination) to show no evidence of syphilis. The relationship of normality to the duration of pediatric follow up will be discussed subsequently. Children showing unmistakable signs of the disease, pathologic, roentgenologic or clinical (including serologic), are recorded as syphilitic. Under a third classification, "no data," were placed all cases presenting insufficient evidence on which to make a diagnosis either of "normal" or of "syphilis." The group designated "no data" included still-born children in whom postmortem and roentgen examination was negative, babies apparently healthy but not followed in

From the Department of Obstetrics and the Syphilis Division of the Medical Clinic, the Johns Hopkins University and Hospital.

¹ Williams, J. W. *Obstetrics*, ed. 5, New York: D. Appleton & Co., 1923, p. 714. 1930 edition, p. 167.

the clinic, and cases in which clinical, pathologic or roentgenologic evidence was questionable. It is assumed that the absence of discoverable changes at autopsy does not necessarily indicate the absence of infection with syphilis. Maceration alone was not considered sufficient evidence for a diagnosis of syphilis. Approximately one third of all infants belong to the "no data" group. In the accompanying tables this group has been omitted for, while among these are of course both syphilitic and normal children, it is a fair statistical assumption that the proportions of each found in the known groups would also be preserved in the unknown groups, and the trend is thereby unaffected.

CRITERIA OF DIAGNOSIS IN THE INFANT

When a living child is born of a syphilitic mother, treated or untreated, it is of paramount importance to determine as promptly as possible whether or not the child is infected. Five methods of examination are available in order of their time relationships to birth, as follows: (1) dark-field examination of the umbilical cord vessels, which may be performed within a few minutes of delivery, (2) the cord Wassermann test, requiring from twenty-four to forty-eight hours for a result, (3) microscopic examination of the placenta the rapidity of reporting depending on the expedition of the pathology laboratory but requiring several days, (4) roentgenograms of the infant's long bones most satisfactory at about the second week of life, and (5) pediatric follow up by clinical and serologic methods necessitating several months of study.

Dark-Field Examination of the Umbilical Cord—This method has not been utilized in our series. It is highly lauded in Germany, especially by Philipp,² whose publications should be consulted for details. If spirochetes are found, the infant is definitely infected. Their absence does not, however, indicate freedom from infection but merely the necessity for further study by other means. The method has been used by one of us but in our opinion is too cumbersome for routine application.

The Cord Wassermann Test—The reliability of the cord Wassermann test has long been a controversial subject. Some observers feel that a positive test is a

necropsy, roentgen and pediatric follow up. Unfortunately, we have no data as to comparative results of maternal and cord Wassermann tests at the moment of delivery, but we are able to offer an opinion as to the reliability of cord Wassermann tests by the second method of study. This information is provided in table 1.

Among infants in whom the Wassermann test on the cord blood was positive, 81.4 per cent were ultimately shown to be syphilitic, while among infants with a negative cord Wassermann reaction, born of a syphilitic mother, only 13.7 per cent proved to have

TABLE 2—Condition of Placenta as Compared with Ultimate Status of Infant

Placenta	Number of Preg- nancies	Ultimate Status of Infant per Cent	
		Normal	Syphilitic
Normal	518	79.0	20.0
Syphilitic	41	12.1	87.8
Questionable	19		100.0

congenital syphilis. It is evident that this test is not an infallible guide to the presence or absence of syphilis in the offspring, but it does provide important information regarding the ultimate diagnosis. A positive test alone is not an indication for immediate treatment but it points strongly to the necessity for further intensive study of the infant.

Placental Histology—Macroscopic and microscopic examination of the placenta was a routine procedure in this series of cases, the diagnosis having been made or confirmed in almost all instances by the late Dr. J. W. Williams. In table 2 are shown statistics indicating the ultimate status of the child when the placenta was regarded as normal, syphilitic or questionably syphilitic.

Among cases in which the placenta was considered to be normal, 20 per cent of the offspring subsequently showed evidences of syphilis while 80 per cent remained free from infection. On the other hand, among cases exhibiting a syphilitic or questionably syphilitic placenta, the baby proved to be syphilitic in all save 8.3 per cent. Microscopic study of the placenta, therefore, affords exceedingly important information regarding infection in the child. If the placenta shows changes due to syphilis, the presence of infection in the infant cannot be ruled out without the most careful study over a period of months although treatment should not be instituted until a definite diagnosis of syphilis has been made. Among cases in which the placenta was normal, however, the child was syphilitic in 20 per cent, thus the occurrence of a normal placenta in no way eliminates the possibility that the child is infected. In actual practice, the value of information obtained by placental examination is somewhat impaired by the fact that among cases showing a syphilitic placenta the child was born alive in only 19 per cent, and even a smaller percentage survived the first few weeks of life. Of eight surviving infants, three were shown to be normal after observation periods of twelve years, eight years and one and one-half years, respectively. The presence of syphilitic changes in the placenta and the apparent absence of syphilis in the fetus raises some interesting questions regarding the mode of infection of the fetus, unfortunately it is not possible to review in detail the basis for the diagnosis in these three cases. Examination of the placenta is one of the important

TABLE 1—Cord Wassermann Reaction as Compared with Ultimate Status of Infant

Negative	283	86.2	13.7
Positive	54	18.6	81.4

definite indication of infection of the fetus, others believe that the passive transfer of reagin from maternal to fetal circulation is common and that the results of this test are without significance. Two methods of approach are available for a solution of this problem: (1) a comparison of the cord with the maternal blood Wassermann reaction at the time of delivery, to determine the relationships of positive or negative cord tests with the reagin titer of the mother's blood; (2) the correlation of cord Wassermann results with the ultimate status of the child, as determined by

2 Philipp E. Die frühzeitige Erkennung und Behandlung der Lues bei Mutter und Kind als sozialhygienisches Problem. Ztschr. f. Geburtsh. u. Gynäk. 93: 443, 1928.

aids, not only in arriving at a correct diagnosis of congenital infection in the child, but also at times in making a correct diagnosis of syphilis in the mother. Cases are still encountered in which the changes in the placenta are the only clue to the presence of syphilis in the mother.

The result of the Wassermann test on the umbilical cord blood and the result of placental examination considered together afford information that is of more value in determining the presence or absence of syphilis in the offspring than when either is used alone (table 3). Thus, among cases in which the cord Wassermann test and the placenta were both positive, the infant proved to be syphilitic in all, while among cases in which both of these were negative the child was syphilitic in only 12.2 per cent.

Moreover, when either of these diagnostic procedures gave positive results the percentage of syphilitic children was considerably higher than when both were normal. The figures in table 3 indicate also that the Wassermann test on the cord blood is a more reliable guide than is the result of placental examination, for the percentage of syphilitic offspring was twice as high among cases in which the cord Wassermann test was positive and the placenta normal than when the results were the reverse.

Roentgenograms of the Infant as a Diagnostic Sign—This subject, including a review of the literature, is thoroughly covered in a series of articles by McLean.³ His observations tend to show that syphilitic epiphysitis is almost universal in syphilitic infants born alive at term. In some instances visible roentgen changes are difficult to detect at birth, but they are almost always apparent by the end of the second week. It is possible

one of the earliest, diagnostic signs of congenital syphilis. Among nineteen cases in our series in which a roentgen diagnosis of syphilis was made, all eventually presented supporting evidence for the diagnosis of syphilis.

From the figures in table 4 it is evident that the absence of demonstrable syphilitic epiphysitis does not rule out the possibility that the child has syphilis, for among sixty-two infected children the roentgen examination was negative in forty-three, or 69.3 per cent.

Pediatric Follow Up—It is certainly true that the blood Wassermann test on the infant at birth is no

TABLE 5—*Pediatric Follow Up*

Questionable	15	2	2	6	2	3		

more reliable than the cord Wassermann test. Many infants who ultimately develop congenital syphilis have negative blood Wassermann reactions during the first few weeks of life. In our clinic, it is routine practice to test the child's blood at the age of 6 weeks. If the test is positive, the diagnosis of syphilis is made even in the absence of clinical or roentgen evidence, if negative, it is repeated at 3 months and 6 months and, when the children can be followed, at even longer intervals.

Unfortunately, our material does not provide an answer to the important practical question of how long a presumably normal infant born of a syphilitic mother should be followed before being discharged as normal. Roberts,⁴ from a study of 903 children born of syphilitic mothers, concluded that, should the infant show no clinical or serologic evidence of the disease by the fourth month of life, infection has probably not taken place. There were occasional exceptions to this rule, however, and it is our opinion that it is safest to follow the child with repeated clinical and serologic examinations for a minimum of six months and, if possible, for two years.

In table 5 we present figures that indicate the actual duration of follow up among the children in this series, these are of value chiefly from the standpoint of the normal group, two thirds of whom have been followed for more than three months after birth.

METHOD OF TREATMENT OF SYPHILITIC MOTHERS

Since its inception, the syphilis clinic of the Johns Hopkins Hospital has employed a treatment scheme consisting essentially of alternating courses of an arsphenamine product and a heavy metal, either mercury or bismuth. The former group of drugs is the more potent form of treatment and it has been customary to use the heavy metal only as interim treatment between courses of an arsphenamine. For the purposes of this paper the amount of arsenical drug received by any patient is expressed in terms of grams of arsphenamine. On the basis of the probable therapeutic index (Schanberg and Kolmer) a given amount of neoarsphenamine is recorded as one-half that amount of arsphenamine. However, since all save a relatively few of our patients received arsphenamine, the results

that students of the problem will not all be willing to agree to the finality of the roentgenologic results as expressed by McLean, in the diagnosis of congenital syphilis for there are instances in which there is room for legitimate differences of opinion in the interpretation of films and in our own series there are many cases in which no epiphysitis was demonstrable despite the fact that subsequently the infant was shown to have syphilis. Nevertheless the presence of characteristic epiphysal lesions as demonstrated roentgenographically affords one of the most definite, as well as

³ McLean, Stafford. *The Osseous Lesions of Congenital Syphilis*. Am J Dis Child 41: 130 (Jan.) 363 (Feb.) 607 (March) 887 (April) 1128 (May) 1411 (June) 1931.

⁴ Roberts, M. H. *Congenital Syphilis*. Am J Dis Child 45: 461 (March) 1933.

published here afford essentially an indication of the effectiveness of this preparation. The individual dose of the drug was found to have been remarkably constant, 0.3 Gm constituting the usual dose for an adult female. A course of six treatments, therefore, would imply an amount of arsphenamine just under 2 Gm, two courses just under 4 Gm, and so on. Arsphenamine in this dosage is well tolerated by the pregnant woman. The pregnant state provides an increased liability for the supposed arsphenamine accident of acute yellow atrophy of the liver, of which we have seen four examples in pregnant women. Arsphenamine therapy does not, however, increase the incidence of other toxemias of pregnancy, it does not cause abortion or miscarriage, though its use in the last week or two of pregnancy may precipitate labor, and it is without deleterious effects on the fetus.

As the heavy metals occupied a position of secondary importance in our treatment scheme, no opinion can be expressed as to their isolated effect. Rarely were these drugs given alone or in quantities out of proportion to the arsphenamines. It is possible, however, to formulate an opinion as to their value when used in conjunction with arsphenamine as compared with arsenical treatment alone.

With these limitations in mind we may analyze the results of antisyphilitic treatment administered at various times in relation to the pregnancy. To 268 patients, no treatment was given either before or during pregnancy, to 82, treatment was given before pregnancy but none during pregnancy, to 391 during pregnancy only, to 202, both before and during pregnancy.

THE OUTCOME OF PREGNANCY IN UNTREATED
SYPHILITIC MOTHERS

Control Group—The chances that an untreated syphilitic woman may bear a normal child have been variously estimated at from one in four to one in twenty-five. In McCord's⁵ series of untreated syph-

ilitic colored women the percentage giving birth to still-born infants was 66.3 in one series of 116, and 80.0 in another series of 137, undoubtedly a large number of the children born alive had syphilis. Gammeltoft,⁶ dealing almost entirely with white women, found 96.5 per cent syphilitic infants among a total of 201 born of untreated syphilitic mothers.

5 McCord J R. Prenatal Treatment of Syphilis. Some Results of Antisyphilitic Treatment in a Series of 519 Pregnant Syphilitic Colored Women. *Am J Syph* 16: 78 (Jan) 1932.
6 Gammeltoft S A. Syphilis and Pregnancy. *Am J Obst & Gynec* 15: 747 (June) 1928.

In our series of 268 pregnancies in which the mother had received no treatment either before or during pregnancy, 45.9 per cent resulted in a still-born infant, and 54.1 per cent were born alive. Among infants in whom the ultimate status is known, as determined by the various methods of study outlined above, 35.4 per cent were normal and 64.5 per cent were demonstrated clinically or at autopsy to have syphilis. It is difficult to appraise the factors accounting for a higher percentage of normal children in our series than in similar groups from some other clinics. It is possible that the routine use of the Wassermann test over a period of

TABLE 7—Effect of the Addition of Heavy Metal to Arsphenamine Therapy During Pregnancy on the Ultimate Outcome in the Child

many years has succeeded in adding to the group of syphilitic mothers many who would otherwise pass unrecognized. It is conceivable, also, that by the use of a sensitive test patients with long standing infections are included who would be more likely than not to give birth to normal children (Kassowitz's law), for it is probable that the Wassermann titer decreases in many patients with increasing lapse of time after infection.

RESULTS OF ANTISYPHILITIC TREATMENT OF
THE MOTHER IN THE OUTCOME
OF PREGNANCY

Treatment During Pregnancy, None Previously—The Optimal Amount of Arsphenamine. The data of table 6, showing the immediate and ultimate outcome as to the child in 650 deliveries occurring in women who had never received any treatment prior to the pregnancy under consideration, are confirmatory of the excellent results presented by many other investigators the world over. In addition, however, these data offer evidence as to the optimal amount of arsphenamine for the child. The 268 pregnancies in untreated women are included as a control. The ultimate status of the child is classified on the basis just described. Even a very small amount of treatment (1 Gm or less of arsphenamine) given in the last month of pregnancy alters the prognosis for the infant in startling fashion in the direction of his chance for ultimate normality. We realize, however, that these data do not present an absolutely accurate picture of the efficacy of treatment, since women who have gone through to the tenth month of pregnancy represent a selected group. We find, however, that, of these women who were untreated and who were delivered of a child of 45 cm or more in length, 51.8 per cent of the offspring were syphilitic and 48.2 per cent nonsyphilitic. Of the treated patients, delivered at term and receiving less than 1 Gm of arsphenamine, only 27 per cent were syphilitic and 73 per cent normal. When it was possible to give as much as 4 Gm (an approximate average of from twelve to fourteen injections) congenital syphilis in the offspring was not observed.

THE USE OF HEAVY METALS IN ADDITION
TO ARSPHENAMINE THERAPY

A point of great practical importance is whether treatment during pregnancy should be limited to the arsphenamines alone, or whether a heavy metal should be added. Our material furnishes an answer (table 7) that can be regarded only as suggestive in view of the fact that the time element of duration of treatment is a factor of considerable importance (table 8).

Comparing only those patients who received 2 or more grams of arsphenamine with and without the addition of bismuth or mercury compounds, the advantage to the child, in terms both of immediate and of ultimate outcome, is significantly in favor of those in whom heavy metals were used. This is particularly striking in the ultimate status of the child. When the mother received some heavy metal during pregnancy the child was normal in 93.4 per cent and syphilitic in 6.5 per cent, as compared with 78.0 and 22.0 per cent, respectively, in infants born of mothers who received arsphenamine alone.

In this particular series of patients the two drugs (arsenical and heavy metal) were used in alternating courses when time permitted, and the mothers who received arsphenamine alone were usually so treated because they first came under observation so late in pregnancy that there was no available time in which to follow a course of arsphenamine with a course of heavy metal. The superior results when this was done, however, may indicate either the desirability of combined treatment or the commencement of treatment early in pregnancy. If treatment can be started early enough (before the fifth month) to permit alternating courses, this should be done.

RELATIONSHIP OF OUTCOME TO THE TIME
OF STARTING TREATMENT

The dosage of antisyphilitic drugs is not the only factor involved in the child's fate. The duration of pregnancy at the start of treatment is equally important. This is analyzed in table 8. The chances of obtaining a living infant are about equal, whether the mother's treatment is started in the first or second half of pregnancy (and in either case, this approximates the inci-

TABLE 8—Outcome as to Child as Influenced by Time of

dence of living children in normal women). But if it is started within the first five months of pregnancy, the probability of the birth of a syphilitic child is less than half as great (8.7 per cent) as when it is delayed until the sixth month or later (22.2 per cent). It is of great importance to note, however, that both the immediate status and the ultimate status of the child are vastly better even if treatment is delayed until the final month of pregnancy than if no treatment at all is given (percentage of living children 89.0, as compared with 77.4, of normal children, 73.0 as compared with 48.2 (table 4). Though prevention of infection of the fetus by means of treatment begun before the fifth month is

easier than its "cure" with treatment given later, nevertheless something of value may be accomplished no matter how late in pregnancy the existence of syphilis is recognized in the mother. Even if she is almost at term, an injection or two of arsphenamine may materially improve the infant's chance of life (table 9).

IMPORTANCE OF CONTINUOUS TREATMENT, AND
OF TREATMENT IN THE LAST TRI-
MESTER OF PREGNANCY

An analysis of the failures of antisyphilitic treatment provides information on two additional points of importance. In fourteen instances, syphilitic babies were born to mothers who received treatment before the beginning of the eighth month. These are listed in detail.

Treatment Started in Seventh Month. Outcome Syphilis in Five—1 Treatment, arsphenamine 20 Gm in seven doses over a period of fourteen weeks. Child living at term. Clinical syphilis.

2 Treatment, arsphenamine 15 Gm in five doses. No treatment during last fifty days of pregnancy. Child still-born at term. Autopsy, syphilis.

3 Treatment, arsphenamine 23 Gm in six doses, but only mercury injections in last sixty days of pregnancy. Child living at term. Clinical syphilis.

4 Treatment, arsphenamine 15 Gm in five doses plus an indefinite amount of mercury by injection. No arsphenamine during last sixty days of pregnancy. Child living at term. Clinical syphilis.

5 Treatment, arsphenamine 0.4 Gm in one dose, neoarsphenamine 27 Gm in six doses, and bismuth salicylate 10 Gm in five doses but only bismuth in last six weeks of pregnancy. Child living at term. Clinical syphilis.

Treatment Started in Sixth Month. Outcome, Syphilis in Three—6 Treatment, arsphenamine 12 Gm in three doses and silver arsphenamine 0.8 Gm in four doses over a period of eighteen weeks. Child living at term. Clinical syphilis.

7 Treatment, arsphenamine 21 Gm in six doses and an undetermined amount of mercury by injection. No arsphenamine during the last twelve weeks of pregnancy. Child living at term. Clinical syphilis.

8 Treatment, only mercury by injection at any time. Child living at term. Clinical syphilis.

Treatment Started in Fifth Month. Outcome Syphilis in Two—9 Treatment, arsphenamine 22 Gm in seven doses plus an undetermined amount of mercury by injection, but only one treatment of arsphenamine during the last nine weeks of pregnancy. Child living at term. Clinical syphilis.

10 Pregnancy resulted in six months abortion after two doses of arsphenamine. Roentgen examination showed syphilitic epiphysitis.

Treatment Started from First to Fourth Month. Outcome, Syphilis in Four—11 Treatment, arsphenamine 18 Gm in six doses plus mercury by injection for four months. No arsphenamine during the last nineteen weeks of pregnancy. Child living at term. Clinical syphilis.

12 Treatment, arsphenamine 0.8 Gm in three doses. No treatment during last twenty-two weeks of pregnancy. Child living at term. Clinical syphilis.

13 Treatment, arsphenamine 2.3 Gm in six doses. No treatment in last twenty-seven weeks of pregnancy. Child living at term. Clinical syphilis.

14 Treatment, arsphenamine 3.9 Gm in eleven doses plus an undetermined amount of mercury by injection over a period of twenty-six weeks. Child still-born. Autopsy, syphilis.

One of two factors is common to all these cases. Either treatment was administered at irregular intervals or no arsphenamine at all was given during the last trimester of pregnancy. It seems clear from these unfortunate instances that it does not suffice to give treatment irregularly or only during the early months of pregnancy, it must be continued regularly and espe-

cially throughout the last trimester. The administration of several doses of an arsphenamine just before delivery seems particularly important.

In table 10 this problem is presented in slightly different form.

Pregnancies resulting in a known syphilitic infant after the mother received 2 Gm or more of arsphenamine are tabulated, included are three patients who received some treatment before pregnancy. Here again it is noted that in many of the cases treatment was irregular, and frequently no arsphenamine was received in the last weeks of pregnancy. This, however, is not true with regard to cases 1, 7, 11, 12, 13 and 15, in which treatment was regular and the amount of each dose not unusually low. The only possible conclusion to be drawn is that treatment up to 4 Gm of arsphenamine or its equivalent, or less than twelve treatments of an arsenical, is simply inadequate, in certain cases, to protect the child from syphilis regardless of the regularity of treatment. A point to be noted in passing

is that in seven of the sixteen cases presented in table 10 the mother had secondary syphilis during pregnancy. As the percentage of early syphilis in this special group is much higher than in the whole series, it would indicate that from 2 to 4 Gm of arsphenamine is less efficient in preventing syphilitic offspring in mothers with early syphilis than in mothers with late syphilis.

cially throughout the last trimester. The administration of several doses of an arsphenamine just before delivery seems particularly important.

In table 10 this problem is presented in slightly different form.

Pregnancies resulting in a known syphilitic infant after the mother received 2 Gm or more of arsphenamine are tabulated, included are three patients who received some treatment before pregnancy. Here again it is noted that in many of the cases treatment was irregular, and frequently no arsphenamine was received in the last weeks of pregnancy. This, however, is not true with regard to cases 1, 7, 11, 12, 13 and 15, in which treatment was regular and the amount of each dose not unusually low. The only possible conclusion to be drawn is that treatment up to 4 Gm of arsphenamine or its equivalent, or less than twelve treatments of an arsenical, is simply inadequate, in certain cases, to protect the child from syphilis regardless of the regularity of treatment. A point to be noted in passing

posely or inadvertently, were not treated during pregnancy. The outcome of pregnancy among this group is shown in table 11.

In 81.7 per cent of cases the child was born alive, the offspring proved ultimately to be normal in 91.3 per cent and syphilitic in only 8.7 per cent of cases in which the ultimate status of the child is known. Viewed as a group, therefore, the results of treatment before pregnancy in these patients were even better than when treatment was given only during pregnancy. Moreover, the results vary in general with the amount of treatment given before pregnancy, for the outcome was much more favorable in patients receiving more than 2 Gm of arsphenamine than in those receiving less than this amount. It would appear from table 11 that 2 Gm or more of arsphenamine before pregnancy is sufficient to protect the child in every instance. However, we have recorded one case, included in table 12, in which the mother received not only 4 Gm of arsphenamine before pregnancy but some treatment dur-

ing pregnancy as well and yet gave birth to a syphilitic baby. In this instance the mother exhibited lesions of tertiary syphilis during pregnancy in spite of previous treatment. Thus, despite the relatively large amount of previous antisyphilitic treatment, the infection was still active and consequently a menace to the child.

Among the group of eighty-two women who were treated prior to but not during pregnancy, twenty had positive Wassermann reactions and fifty-one had negative reactions during pregnancy, while in the remainder no reaction was recorded. Among the twenty patients with a positive Wassermann reaction the ultimate status of the child was normal in five, syphilitic in four, "no data" in eleven. Among the mothers exhibiting a negative Wassermann reaction the outcome as regards the child was normal in thirty-three, syphilitic in none, "no data" in eighteen. In other words, the four known syphilitic infants in this group belonged to mothers with positive Wassermann reactions.

It appears, therefore, that if, in spite of previous treatment, the blood Wassermann reaction remains positive, or if the patient has developed active lesions of syphilis, the amount of previous treatment should be disregarded and the patient treated as would be any other with active syphilis. On the other hand, if the mother has been thoroughly treated before pregnancy and has remained clinically and serologically negative for at least a year after the end of treatment, it is probably permissible to withhold treatment during pregnancy.

TREATMENT BOTH BEFORE AND DURING PREGNANCY

As might be expected, the outcome of pregnancy in women treated both before and during pregnancy is even more favorable than when treatment is given either before or during pregnancy alone. The outcome

TABLE 11—Effect of Treatment of the Mother Before Pregnancy, None During Pregnancy on Outcome of Child

of pregnancy in 202 cases is shown in table 12. Among this group the percentage of living children is quite as high as that which might be encountered among a similar group of nonsyphilitic mothers. Moreover, of 135 children whose ultimate status is known, 129, or 95.5 per cent, were normal. Three syphilitic children were born to mothers who received a known amount of treatment in two cases less than 4 Gm. of arsphenamine had been given either before or during preg-

nancy. In the third case, referred to in a preceding paragraph the mother exhibited signs of active syphilis during pregnancy despite large amounts of treatment prior to conception.

SUMMARY

Nine hundred and forty-three pregnancies occurring in syphilitic women were analyzed with regard to the presence or absence of congenital syphilis in the offspring, particular attention being paid to the effect of maternal antisyphilitic treatment on the outcome of

pregnancy. In addition, the relative value in the diagnosis of congenital syphilis of such signs as the cord Wassermann test, placental histology, and roentgen examination of the infant's bones for syphilitic epiphysitis were considered. Among cases showing a negative cord Wassermann reaction the infant was nonsyphilitic in 86.2 per cent, and among those giving a positive reaction the infant was normal in only 18.6 per cent.

Among cases in which the placenta was normal on macroscopic and microscopic examination the infant proved to be nonsyphilitic in 79.9 per cent, while among cases showing syphilitic changes in the placenta the offspring was syphilitic in all but 12.1 per cent. When these two diagnostic aids were considered together, the information was of more value than when each was considered alone. Infants presenting evidences of syphilitic epiphysitis invariably exhibited other evidences of congenital syphilis. However, among children showing no abnormalities on roentgen examination, 20.5 per cent were subsequently shown to have congenital syphilis.

The striking beneficial effect of antenatal arsphenamine therapy is shown by the fact that among pregnancies occurring in untreated syphilitic mothers the infant was born alive in only 54.1 per cent and 64.5 per cent of living offspring were syphilitic, while the administration of as little as 1 Gm. or less of arsphenamine changed these figures to 89 and 27 per cent, respectively. Administration of larger amounts of arsphenamine or related products brought about a further reduction in fetal mortality and in the percentage of syphilitic offspring, until when as much as 4 Gm. (from twelve to fourteen injections) was given no syphilitic offspring was observed. The administration of heavy metals, mercury or bismuth compounds in addition to arsphenamine, enhanced the good results achieved with the latter alone. Better results were obtained when maternal treatment was started in the first half of pregnancy than when begun in the latter half. It was found particularly important, however,

that the arsenicals be given in the two months immediately preceding delivery

The results in cases treated before pregnancy and not during pregnancy were, in general, quite as good as when the mother was treated during pregnancy only. Here, however, the status of the syphilitic infection in the mother is probably the important factor.

Antisyphilitic treatment both before and during pregnancy yielded results superior to treatment during either period alone.

CONCLUSIONS

1 The Wassermann test on the blood of the umbilical cord and study of the placental histology are important aids in the diagnosis of congenital syphilis and should be carried out on all patients not proved during pregnancy to be free from syphilis. Of the two, the former is the more reliable.

2 The presence of characteristic changes in the epiphyses of the long bones during the first two weeks of life is diagnostic of congenital syphilis, but the absence of epiphyseal abnormalities does not rule out congenital infection.

3 Antenatal treatment of pregnant syphilitic patients with arsphenamine reduces the percentage of fetal deaths and the percentage of syphilitic infants in a striking manner. The good results are roughly proportional to the amount of treatment given and the time at which it is started, even a few treatments in the last weeks of pregnancy, however, will materially alter the outcome.

THE POSTTRAUMATIC NEUROSES

GEORGE W. HALL, M.D.

AND

ROLAND P. MACKAY, M.D.

CHICAGO

One of the oldest questions which trouble the mind of the physician is that pertaining to those frequent and baffling nervous states following trauma. The number and importance of these conditions seem to be increasing with the widespread use of machinery in modern industry and transportation. No physician can escape these cases, and all are daily impressed with the great loss of time and money, both to the employer and to the patient, which they bring about. An age-old conflict is being waged today, as in years gone by, between the exponents of the so-called organic and functional interpretations of these conditions. Before the day of Charcot, the explanation was usually sought in organic disturbances of the nervous system, but this great French neurologist early recognized the potent role played by emotional factors. The earliest work of Sigmund Freud, while a student of Charcot's, was in connection with patients exhibiting neurotic states following injury, and since those days it has been generally recognized that the conception of the posttraumatic neurosis was a valuable and valid one. In the past few years, however, an attempt has been made to explain the nervous states consequent to injury—and particularly injury to the head—on organic lesions of the nervous system. This renewed emphasis on the organic factor is largely attributable to the relatively new methods of encephalography and ventriculography and the recent studies of the mechanics of the cerebro-

spinal fluid. The introduction of the method of encephalography has especially given rise to a great deal of enthusiasm and a great wealth of observations in patients who have suffered head trauma. The whole theory of the mechanical etiology of epilepsy has arisen from this movement, and the attempt is being made to explain great numbers of other symptoms on the basis of a disturbance in the hydrodynamics of the cerebrospinal fluid. Many other, so-called finer, methods of study have been utilized in the attempt to find an organic cause for the posttraumatic syndromes.

We do not wish to minimize the importance or value of this attempt. Unquestionably, profit will eventually accrue from these new observations in a broader understanding of the pathologic physiology of head injury. There is, however, a grave danger of being swept off one's feet by overconfidence in a mechanical method. For instance, Strauss and Savitsky¹ state that the term "posttraumatic neurosis" should be abandoned and all the sequelae of head injury explained on the basis of cerebral pathologic changes. While recognizing the great value of these workers' contributions, we feel the need of a new exposition of the psychologic factors underlying the neuroses occurring after head trauma. The neuroses following injury to the head do not differ materially from those after injury to other parts of the body, where no injury to the central nervous system can be in question. Consequently, it seems unwarranted to abandon the concept of neurosis following head trauma, and there appears to be greater need than ever of a proper understanding of these emotional shipwrecks.

It should be made clear at the outset that the diagnosis of a neurosis is not a diagnosis of exclusion. The day is long since past when the term "neurosis," posttraumatic or other, was a waste-basket into which was thrown diagnostic failures. These "functional" disturbances are, on the other hand, recognizable by their own symptomatology, a symptomatology of which an unfortunately large part of the medical profession is quite ignorant.

CLINICAL FEATURES

What are the diagnostic criteria by which the posttraumatic, as well as the nontraumatic, neuroses may be recognized? A study of great numbers of these patients reveals at once that the posttraumatic neuroses do not differ in any essential way from most other, nontraumatic, neuroses. They can all be divided into groups of considerable clinical value, according to their outstanding symptomatology. The following classification includes the majority of cases.

Posttraumatic Neurasthenia—Cases falling into this group exhibit abnormal fatigue and irritability as their outstanding clinical characteristics. This fatigue and irritability are different from those seen in cases of debility from organic disease, in that they are associated with extreme emotionalism and a disproportion between the actual strength of the patient and his supposed weakness. This syndrome is thus rather well described as posttraumatic irritable weakness with emotionalism.

Posttraumatic Anxiety Neurosis—With these patients there is a vast anxiety, which manifests itself with regard to insignificant or imaginary dangers. There is nearly always a marked hypochondria, which is expressed in the patient's concern over one special

or many detailed somatic complaints. These complaints are related most often to the part of the body that was injured, but they are frequently so numerous and bizarre as to render their explanation on an organic basis impossible.

Headache is the most common symptom encountered after head injury. That this headache may be related to "organic" changes is well known, and Foster Kennedy² has recently pointed out the criteria by which it may be recognized. The anxiety headache, on the one hand, is recognizable in that it is usually not a true pain but rather a sense of weight or pressure, is often occipital or vertical in distribution, and is very often constantly present without intermission for days and weeks, being increased only by emotional excitement. Practically all headaches of "organic" origin are, on the other hand, intermittent. The hypochondria in these patients may concern itself chiefly with one organ or symptom until it becomes almost an obsession. In addition, the patient with an anxiety neurosis usually exhibits excessive sweating, cold, clammy hands, tremulousness and dilated pupils—all symptoms of sympathetic overstimulation. The posttraumatic anxiety neurosis can thus be briefly described as exhibiting anxious hypochondria with excessive sympathetic stimulation.

Posttraumatic Hysteria—This is perhaps the most common of the "functional" nervous conditions seen after trauma, although perhaps rare in its pure state. Patients with this type of neurosis exhibit pseudo-organic—usually neurologic—signs and symptoms, such as blindness, deafness, paralysis, anesthetics, and disturbances of motion or gait. These signs can almost invariably be demonstrated to be nonanatomic, i.e., the paralyses, anesthetics and so on do not correspond to the actual anatomic relationships but rather to the patient's idea of the anatomic relationships. Examples of such signs are "stocking and glove" anesthetics, complete paraplegia without sphincter disturbances, and the like. In addition, these patients manifest an abnormal degree of suggestibility. For example, the nonanatomic anesthetics can be altered at the suggestion of the physician. Such a finding, of course, quite excludes an "organic" origin for the sign.

This description would be inadequate if it did not point out that these forms of the posttraumatic neuroses are most often combined rather than pure. One sees regularly anxiety neurasthenia and anxiety hysteria in which the signs and symptoms are mixed.

In addition to these more or less standardized clinical manifestations there are other features in connection with these posttraumatic neuroses which make their recognition more certain. The peculiar emotional state of the patient is almost always diagnostic, being a combination of fear of disability (anxiety), resentment toward the agent responsible for the injury and toward any one, such as the doctor, suggesting that the injury is physically negligible, and a determination to prove beyond a doubt that the injury is "real", i.e., "organic". Also, the disability following the injury is always used to explain the inability of the patient to meet his problems. He can't work, earn money or satisfy his domestic demands because of this particular injury. Furthermore, the reaction of the patient to therapeutic effort is almost always characteristic, there is a tendency to blame any medicine or other therapeutic mea-

sures for the continuation or exacerbation of these symptoms. All methods fail or fall short of their complete purpose, and the doctor begins to feel sure that the patient lacks a real desire to get well. In severe cases these numerous, bizarre and stubborn symptoms, which the physician cannot explain by any known laws of anatomy or physiology, together with the peculiar mental attitude of the patient, constitute a therapeutic problem that is familiar and puzzling to all physicians and that they often eventually are glad to abandon unsolved when the patient, discouraged, seeks aid elsewhere.

PSYCHOLOGY OF THE POSTTRAUMATIC NEUROSES

To attempt to explain these syndromes by recourse to encephalographic, serologic, otoneurologic and various other mechanical methods is to show oneself unfamiliar with the complexity and delicacy of the disturbances from which these patients suffer. In particular, the encephalogram is unsuited to the elucidation of the difficulty, however valuable it may be in other conditions. Apart from abnormalities of the ventricles, gross, localized atrophy of the brain, and distortions of the cerebrospinal pathways by cicatricial contractions and so on, it is our opinion that the encephalogram cannot yet be interpreted with assurance. Furthermore, just what constitutes a normal encephalogram has not been finally established. To one having experience with these neurotic patients, it seems obvious that they suffer largely from emotional and psychologic, rather than physical, difficulty. Consequently, without entering into the old and sterile question as to the relationships between the mind and the brain, it is obvious that, at the present stage of knowledge, it is futile to approach the posttraumatic neuroses from the anatomic or pathologic aspect, and that, at least for the present, it must be studied from the psychologic standpoint, for the purpose of both diagnosis and therapy. One cannot pretend to understand the psychology of the posttraumatic neuroses in all cases because of the extraordinary variety of human nature and the multiplicity of the issues involved. However, a summary of present views can be given in the hope that even a partial understanding will lead to more effective diagnosis and treatment of these unfortunate patients.

One of the first facts that impress one when the history of these patients is carefully studied is that there were evidences of marked neurosis or marked ineffectiveness in the personality before the particular injury in question. This has also been pointed out by other observers³ but is often difficult to demonstrate, since these patients hide evidences of any trouble they may have had previous to the injury. Aside from direct observation, the fact that only certain people develop posttraumatic neuroses, while others with severe injuries do not, suggests that some preexisting factor must have been present to determine the development of the neurosis. It is, indeed, notorious that great numbers of patients who have received the most severe injuries do not develop a neurosis, while in others the slightest injury suffices to precipitate a severe nervous state.⁴ These facts suggest very strongly that people who develop posttraumatic neuroses already had the psychologic basis for the breakdown, and that the injury served merely as a precipitant.

⁴ Freud, Sigmund. Beyond the Pleasure Principle. London: International Psychoanalytical Press.

That this is true is suggested also by the observations of Schaller and Somers,⁵ who found that after recovery from a posttraumatic neurosis had begun a certain point was reached when recovery ceased and the patient remained at a standstill or retrogressed. It thus appeared that, after the immediate illness had been alleviated, the untoward circumstances in connection with the injury adjusted, the fight for compensation ended, the repeated medical examinations stopped, and the patient back at work, there still persisted a personality defect which rendered the patient subnormal. Therefore, the patient who suffers from a posttraumatic neurosis must be considered already abnormal before the injury. The reason for this abnormality, this personality defect, is, therefore, to be traced much further back than the injury, since it existed prior to the injury.

The ultimate understanding and treatment of the posttraumatic neurosis thus involves a fundamental psychologic study of the individual in his relationships to himself, his environment and his associates. Such study leads inevitably to childhood, early home conditions, and the establishment of undesirable behavior tendencies in early life. These behavior tendencies consist largely in an increased self centeredness, a feeling of inferiority, an improper and often unduly antagonistic attitude toward authority, and an inability to face difficulty with courage, rather seeking refuge in excuses and in illness.

It will be profitable at this point to cite briefly a case seen in St. Luke's neurologic outpatient department by Dr. T. L. Fentress and one of us (R. P. M.).

H. V., a carpenter, aged 45, came to the clinic complaining of generalized weakness, painful back, attacks of numbness in his arms and legs, occasional headaches (especially distributed over the occipital region), insomnia, irritability, inability to lie on his left side because of pain in his arms, discomfort during defecation, and anxiety about his cervical spine and occipital region, together with loss of memory which he attributed to a growth at the base of his brain. These complaints he dated back to an accident that occurred in April, 1932 when he fell a short distance from a ladder and struck the occiput. He was not rendered unconscious and continued to work. However one month after this accident he lost his job and thereafter began to suffer from pain in the occiput and neck. For this trouble he sought medical aid, and the physician, taking a serious view of the affair, urged that roentgen examinations and other expensive tests be made, for all of which the patient did not have sufficient money. Thereupon the physician urged the patient to sue the company for which he worked when injured, attributing his troubles to the fall from the ladder. He was urged into this suit also by his wife. The suit was unsuccessful whereupon the other numerous symptoms already mentioned developed. In spite of many examinations and much treatment, his condition had persisted and even grown worse.

The general and neurologic examinations were objectively negative, except that the patient was exceedingly anxious and tremulous, his hands were cold and dripping with perspiration, his axillae were constantly sweating so that the drops ran down his sides during the examination, his pupils were large and his whole mental state was chaotic. It was impossible to detect objective evidence of any organic disease.

At this point the detailed past history of the patient will be of interest. He was the youngest child in his family and his father died when the patient was 3 years of age. Being the youngest he became his mother's favorite and was sheltered and protected by her from his earliest life. She defended him against his playmates, made all his decisions for him, humored him in his slightest wishes and when he grew up would never go to bed until he was safely back at home. She sympathized

with him in all his difficulties and comforted him by laying the blame always on others when he encountered boyhood troubles.

Eventually his mother became an invalid and he went to live with his older brother and his wife. Here the history was repeated. His brother's wife humored and catered to him even as his mother had done. At the age of 22 he married, but of this marriage we know little except that two children were born. At the age of 30 he lost his wife and one son in an influenza epidemic and finally he remarried about the time he received the injury to his head. His second wife accompanied him to the clinic. She was a strong and aggressive type of woman, a former trained nurse, who answered questions for him and obviously did his thinking for him, and humored and dominated him.

This patient illustrates well many of the points which have already been made in this paper. His case is properly diagnosed as one of posttraumatic anxiety neurosis. It is quite clear, even on reciting the list of the patient's complaints, that no conceivable injury that he could have received in his fall could have caused all his trouble, in fact, he suffered but little inconvenience from his fall until a month later, after he had lost his job, i. e., met a difficulty he could not, in these times, solve. In addition, it should be obvious from the detailed past history of his life that he did not receive the entire neurosis from the relatively unimportant injury. This man's whole attitude toward life had been misshapen since childhood, his mother, during his most impressionable years, had through excess of care and solicitude, trained him in indecision, lack of self confidence and, worse still, in a habit of playing for sympathy and pitying himself. Later, he demanded and got the same treatment from his older sister-in-law, and, finally, came to the clinic with a wife treating him in the same manner. Can it be doubted that he had chosen this wife because of her resemblance to his mother in this respect? The unfavorable influence exerted by the physician who first saw this patient is worthy of the most serious consideration. With such patients, physicians must be very careful that they do not do more harm than they can possibly do good.

We do not wish to leave the impression that this is the only way in which factors in early life operate to make human beings especially susceptible to posttraumatic neuroses. Undoubtedly, other methods of mishandling children produce similar results. Indeed, it is probable that whether a person develops neurasthenia, the anxiety neurosis or hysteria depends, for the most part, on the particular unfavorable childhood influences. Lack of time prevents us from discussing here the method of development of these other neuroses. We wish simply to emphasize the fact that posttraumatic neuroses are due to factors dating back to childhood, that they are merely precipitated and not really caused by the injury, and that in no sense can they be considered as due to "organic" changes in the brain, as some so fondly imagine.

One further important feature of these neuroses must be emphasized, and that is the unconscious nature of their operation. No proper understanding of these patients can be attained without a recognition of the unconscious nature of the fundamental difficulty. In the case cited, the neurotic behavior of the patient was the only behavior he knew in the face of difficulty. It was a habit as unconscious as his manner of walking or the intonation of his speech. The assumption that such patients are consciously simulating disease does them an injustice and tends to increase still further their difficulty of adjustment and to prevent finally any proper understanding of their condition.

⁵ Schaller, Walter and Somers, M. R. Psychogenic Factors and Precipitation Point in the Posttraumatic Neuroses. J. A. M. A. 93: 967-971 (Sept. 23) 1929.

TREATMENT

The treatment of the posttraumatic neuroses is one of the most difficult tasks facing the physician. The fundamental nature of the personality defect and the early age at which it is established make its eradication a herculean task. It amounts, in effect, to the reeducation of the individual in a new attitude toward life and its problems, which is, of course, especially in older persons, all but impossible. This reeducation is especially difficult because it involves training in a self-centered, egoistic individual to have less concern about himself and more about the outside world. However, very often a partial adjustment can be effected. Certain fundamental rules for accomplishing this can be laid down.

In the first place, it is folly to antagonize the patient by arguing with him. To adopt the attitude that he has suffered no physical injury may be necessary, but one should not, therefore, insist that he has no real symptoms. The prime rule here is to make oneself the patient's friend, to secure his confidence, and to appear to be his ally. This involves listening patiently to his story and cooperating with him in his efforts to recuperate.

When this has been done, it is absolutely necessary that all financial controversy be settled once and for all. All settlements of a monetary sort should be made in a so-called lump sum and not in protracted payments intended to continue until the patient is again well. Such long-continued payments have the effect of placing a premium on his illness and keeping the question of his disability constantly open. This point has been repeatedly made by many authors in the past, including one of us (G. W. H.). The final settlement of all claims at once stops litigation and ends all controversy calculated to keep the patient forever insisting on the seriousness and reality of his injury.

The next step is the reestablishment of the patient as soon as may be possible, in some form of work in which he can effect a transfer of his attention from himself to outside interests. This step is very difficult sometimes and may be possible only after intensive suggestion. One must be careful to give the patient some excuse for recovery. To expect the patient to become free from all symptoms without treatment is almost equivalent to expecting him to admit that his symptoms were "unreal." Therefore, medication, various forms of physical therapy or electrotherapy are very useful in giving him reason to expect improvement and a basis for relinquishing his symptoms. That such treatment may lack a physiologic rationale, in view of the fact that no physical basis exists for his symptoms, is neither here nor there. The psychologic rationale is ample warrant for such procedure. With these methods, encouragement and optimism find an important place when used tactfully and reasonably.

Such methods, however, must not be unduly prolonged, as they only fix the patient's attention too firmly on his ailments. Consequently a judicious relinquishment of the treatment must be practiced.

With such an approach, the treatment of the posttraumatic neuroses will achieve no little success. Physicians can at least avoid causing patients no end of harm by unwise sympathy, apprehension over their condition, and suggestion of further symptoms. There is a place here for great tact and appreciation of human nature, qualities that can come only with long experience in dealing with these unfortunate patients.

MENINGITIS DUE TO THE INFLUENZA
BACILLUS OF PFEIFFER (HEMO-
PHILUS INFLUENZAE)

A STUDY OF ONE HUNDRED AND ELEVEN CASES,
WITH FOUR RECOVERIES

JOSEPHINE B. NEAL, M.D.
HENRY WIRT JACKSON, M.D.
AND
EMANUEL APPELBAUM, M.D.
NEW YORK

The first authentic case of influenza bacillus meningitis was described by Slawyk¹ in 1899. Pfeiffer himself supervised the bacteriologic work. Earlier cases in which gram-negative bacilli were demonstrated were reported by Pfuhl,² Haedke³ and Fraenkel,⁴ but the bacteriologic studies were inconclusive. During the years that followed a few scattered cases were reported but it was not until 1911 that a real impetus was given to the study of influenza bacillus meningitis by Dr. Martha Wollstein⁵ who reported eight cases that she had studied in a little more than a year. She made a careful analysis of the spinal fluids and did virulence tests on the strains of the bacilli, including the experimental production of the disease in monkeys, and treated successfully two of these monkeys with a serum that she had prepared by immunizing goats. In these publications the literature was carefully reviewed.

TABLE 1—Distribution of Most Common Forms of Meningitis

Meningococcal meningitis	1,216
Tuberculous meningitis	961
Pneumococcal meningitis	209
Streptococcal meningitis	203
Influenza bacillus meningitis	111
Staphylococcal meningitis	27

Since 1911 numerous articles on influenza bacillus meningitis have appeared, but most of these referred to small numbers of cases. In 1921 thirty-two cases with one recovery were reported by Dr. Josephine B. Neal.⁶ After a careful study of all factors bearing on influenzal meningitis and a complete review of the literature, Rivers,⁷ in 1922, reported twenty-three cases with one recovery.

Jenks and Radbill⁸ described thirty-two cases of influenza bacillus meningitis with no recoveries, occurring from 1921 to 1929.

Hart⁹ reported thirty-two cases with two recoveries. Our main object in this paper is to report 111 cases that we have seen in the past twenty-three years in connection with our study of meningitis and other acute infections of the central nervous system.

Influenza bacillus meningitis ranks fourth among the types of purulent meningitis. Table 1 shows the distribution of the most common forms of meningitis that we have seen.

The symptomatology of influenza bacillus meningitis differs in no way from that of meningococcic meningitis. Since so large a percentage of cases occurs in infancy, it may be well to emphasize that the early symptoms at this age are not conspicuously referable to the central nervous system. The earliest signs are usually those of a gastro-intestinal disturbance, irregular fever, irritability and a bulging fontanel. A diagnosis

TABLE 2—*Distribution by Age and by Sex*

Age of Patient	Sex		Total Number of Cases
	Male	Female	
1 2 3 months	1	2	3
4 5 6 months	6	8	14
7 8 9 10 11 12 months	8	9	17
Total under 1 year	15	13	34

60 to 70 years	0	1	1
Total	52	59	111

at this stage can be made only by lumbar puncture, and this is indicated in babies who are sick with indefinite symptoms that do not yield readily to treatment.

Table 2 summarizes the distribution by age and sex.

Influenza bacillus meningitis is essentially a disease of infancy and early childhood. More cases occurred in the first year of life than in any other one year, and more than half of the total number of cases (sixty-two) occurred in the first two years of life. More cases occurred in females than in males. This is contrary to the distribution in meningococcic meningitis, poliomyelitis and epidemic encephalitis.

Ten of the 111 cases were in Negroes. This is a very much higher proportion than occurred in other acute infections of the central nervous system, except perhaps in tuberculous meningitis.

Table 3 shows the incidence of the cases by year and by season. By far the largest number of cases occur in the last quarter of the year, following closely the peak of the curve of pneumonia incidence. In meningococcic meningitis the largest number of cases occur during the first half of the year. The distribution by year shows nothing notable except that during the influenza epidemic in 1918 and 1919 there was no increase in the number of cases of influenza bacillus meningitis. The largest number of cases was seen in 1932, a year that was not marked by any unusual incidence of infection of the upper respiratory tract in New York.

There has been a great deal of discussion as to whether influenza bacillus meningitis is a primary or a secondary disease. In the earlier days when B influenzae was considered the cause of clinical influenza, many observers expressed the opinion that influenza bacillus meningitis was a complication of a respiratory infection.

Rivers⁷ states that 74 per cent of 171 cases studied by him were probably primary infections. He also calls attention to the fact that, in not a few instances, pneumonia and other lesions accompanying the meningitis are not due to the influenza bacilli.

Hart⁹ states that ten of his thirty-two cases appeared to be primary and that in practically none was it a complication of a respiratory infection.

Of our 111 cases, 68, or 61 per cent, were apparently primary.

In many other instances the preceding or concomitant pneumonia, otitis media or other lesions were in all probability not caused by the influenza bacillus. Since this fact has been brought out by other writers, it seems fair to assume that in a large percentage of cases influenza bacillus meningitis is a primary disease.

We have done blood cultures on eight of our patients and, of these, seven were positive. In other cases there was evidence of a generalized infection, for instance, five patients had a hemorrhagic rash and three patients had joint involvement, in one of which the organisms were recovered from the purulent joint exudate. Rivers⁷ reported eight positive blood cultures in eighteen cases but believed that with suitable mediums the percentage would have been higher. Hart⁹ did blood cultures in seven instances, of which four were positive.

LABORATORY EXAMINATION

Blood cultures should be done more regularly in influenza bacillus meningitis. The blood count shows a high polymorphonuclear leukocytosis. In our own series the leukocytes ranged from 9,000 to 36,000, and the polymorphonuclears ran as high as 92 per cent. Rivers,⁷ Jenks and Radbill,⁸ and Hart⁹ report similar observations.

The spinal fluid examination in influenza bacillus meningitis differs in no way from other forms of purulent meningitis. The fluid is cloudy to purulent in appearance and shows a marked pleocytosis with a preponderance of polymorphonuclears, a variable increase in protein and, when the disease is well established, a decided decrease in the sugar content. The influenza

bacillus is demonstrated by smear and culture. A positive diagnosis must be made by cultural examination.

It is interesting to note that strains of the influenza bacillus isolated from cases of influenza bacillus meningitis tend to fall into one group, while the strains of the bacillus obtained from other sources show no tendency to grouping. This was first demonstrated by Povitzky¹⁰ in our laboratories and was subsequently corroborated by Rivers and Kohn.¹¹ Out of fifty-eight

¹⁰ Povitzky, Olga R. and Denny, H. T. *J. Immunol.* 6: 65 (Jan) 1921.

cultures studied by Povitzky, twenty-seven were identical with the predominating group, eighteen were closely related to the predominating group and thirteen were heterogeneous. The bacteriology of influenza bacillus meningitis is described in detail by Povitzky^{11a} in another paper.

PATHOLOGY

The lesions in influenza bacillus meningitis differ in no essential particular from those found in other forms of purulent meningitis. The brain is usually tense, congested and edematous. Occasionally there is distinct flattening of the convolutions. There may be marked engorgement of the superficial cerebral vessels without any conspicuous exudate. More often, however, the surface of the brain is covered with a patchy, yellowish green, thick, purulent exudate, which is most abundant at the base, surrounding the optic chiasm, the peduncles, the inferior surface of the pons and medulla and frequently the cranial nerves. Accompanying the blood vessels, the exudate extends up also on the convex surfaces of the brain. There may be thrombi in any of the cerebral sinuses or in the meningeal veins of the convexity. Frequently there are scattered over the brain surface minute hemorrhagic spots.

The ventricles are, as a rule, distended and contain a turbid or purulent fluid. In protracted cases, however, the ventricular fluid may be clear. On rare occasions there are ventricular hemorrhages. The choroid plexus is usually found extremely engorged and covered with a greenish, fibrinous exudate.

The superficial layers of the brain substance are almost invariably involved, showing engorgement of the vessels and numerous diffuse hemorrhagic areas. In the protracted cases there may be considerable involvement of the cerebral parenchyma. In instances of very severe infection there may occur extensive tissue necrosis in the involved portions of the brain. Minute abscesses may be present, in rare instances, large abscesses occur.

Microscopic examination shows that the exudate which infiltrates the pia-arachnoid consists of fibrin, a large number of polymorphonuclear leukocytes, a few red corpuscles, lymphocytes and large polyblasts. Occasionally the predominant cell may be mononuclear. There is marked vascular congestion with margination of leukocytes. The superficial layers of the brain in the inflamed areas often show minute hemorrhages and very marked cell infiltration. There may be perivascular lymphocytic infiltration. Various stages of degeneration can usually be demonstrated in the neurons.

Changes similar to those just described may be found in the cord, but these, as a rule, are much less severe than those in the brain. The inflammatory process may extend along the anterior or posterior nerve roots.

In protracted cases there may occur an organization of the exudate, with the formation of fibrous strands in the meninges, particularly at the base of the brain. These changes may lead to the development of an internal hydrocephalus. Many clinicians have assumed that extensive adhesions are more common in influenzal than in other forms of purulent meningitis. In our pathologic study we have not been able to confirm this assumption.

It may be of interest to mention briefly the changes in other parts of the body. Toxic degenerative changes in the liver and kidneys are quite common. Broncho-

pneumonia is fairly common. Endocarditis and acute splenitis occur occasionally. In rare instances inflammatory and degenerative changes in the suprarenals have been observed. Arthritis, peritonitis and gastritis are occasionally found. Otitis media, mastoiditis or sinusitis are found not infrequently, but these are not necessarily caused by the influenza bacillus.

COURSE OF THE DISEASE AND TREATMENT

While influenza bacillus meningitis may occasionally run a fulminating course, the disease is frequently prolonged. This has been commented on by many writers. In our series of cases the duration in the greatest number was between ten and twenty days. In thirteen cases it was between thirty and sixty days or longer. This prolonged duration makes it possible to test out different forms of treatment. In searching for methods of therapy, efforts have naturally been made to produce an effective serum.

The first serum for the treatment of influenza bacillus meningitis was developed by Wollstein,¹² who immunized goats with strains of the influenza bacillus and was able to treat successfully two monkeys in which she had produced influenza bacillus meningitis experimentally. This serum was used in two recoveries reported by Torrey.¹³ We have used this serum in five cases, in three of these only one or two injections were given, in the other two, the injections were repeated about ten times in one instance and fifteen times in the other. The last two patients showed temporary improvement clinically, the organisms decreased greatly in number and became largely intracellular, but death finally resulted.

Since 1920, horses have been immunized at the research laboratory in New York City with strains of the influenza bacillus found by Povitzky to predominate in cultures of spinal fluids from cases of influenza bacillus meningitis.

Antinfluenza serum has also been prepared under the direction of Dr Dorothy Wilkes-Weiss of Washington University, St. Louis, and by Hugh K. Ward and Joyce Wright¹⁴ of Harvard.

For the last two years, Dr Margaret Pittman has been preparing a serum at Rockefeller Institute, and there is to be published a report of cases treated under her direction.

With any form of treatment, the mortality has been exceedingly high. Bloom¹⁴ collected from the literature up to March, 1930, a total of 302 cases with a mortality of 92.05 per cent. Of our 111 patients, four recovered, giving a mortality of 96.4 per cent.

Table 4 gives a list of recoveries collected from the literature, to which we have added three of our own and one reported to us personally by Dr Benjamin Kramer. Undoubtedly a number of recoveries have never appeared in the literature.

A study of the treatment of these thirty-five patients who recovered shows that twenty-six had lumbar punctures only or lumbar punctures supplemented by non-specific therapeutic measures. The use of "convalescent serum" is mentioned in three instances. This, however, cannot be regarded as specific therapy, since the serum was obtained from individuals who had recovered from clinical influenza, which is not now considered to be caused by the influenza bacillus. It seems obvious, therefore, that lumbar puncture is an important thera-

¹⁴ Bloom C. J. *New Orleans M & S J* 83 455 (Jan.) 1931

peutic measure. Furthermore, the use of antimeningococcus serum may be of value in a nonspecific manner. Two patients received an autogenous vaccine, and in one of these the antinfluenza serum also was used. Only eight patients received the antinfluenza serum. Of these, four patients were in our own group, and, as will be discussed later, in none of them could the use of the specific serum be regarded as a determining factor in the recovery. However, we have observed a number of instances in which the use of the serum has been followed by a period of improvement, remarkable though temporary, in the patient's clinical condition and in the spinal fluid finding.

There has been a tendency of late to employ the intracarotid route for the injection of serum and chemical agents in cases of meningitis. We have never used nor advocated this method. In the first place, we can see no advantage from its use, since the rapidity of the circulation of the blood is so great. In the second place, one instance has been under our observation and others have been reported to us in which thrombosis of the cerebral vessels followed this method of injection. We therefore regard it as a dangerous procedure.

There is a certain vogue at present for adding complement to the serum in treating cases of influenza bacillus meningitis. From a theoretical standpoint and

We strongly favor that further research be done in an effort to produce more potent specific serum. A study of the pathologic condition shows evidence of a diffuse toxemia, as evidenced by the toxic degeneration of many of the viscera. This was strikingly brought out in one patient who showed definite clinical improvement following the use of the serum intraspinally but who finally died. The necropsy revealed the fact that the meningitis had practically subsided, but there were severe toxic changes in many of the viscera.

This suggests the advisability of attempting to develop a highly antitoxic serum. Furthermore, the frequency of positive blood cultures and also the markedly toxic changes in the viscera indicate the use of the serum intravenously as well as intraspinally in the early stages of the disease.

from the results in certain cases under our observation, we fail to see that it is of any value.

The method of application and the underlying principles of forced drainage of the cerebrospinal fluid in cases of influenza bacillus meningitis have been studied thoroughly by Kubie¹⁵ and will not be discussed in this paper. It is conceivable that a thorough "washing out" of the exudate from the perivascular tissues of the brain may also effect a marked elimination of toxins and in this way may influence favorably the course of the disease. We have employed this method of drainage in the last ten cases in our series, with apparent benefit.

15 Kubie L. S. and Shultz G. M. Bull Johns Hopkins Hosp 37 91 (Aug) 1925. Kubie L. S. Intracranial Pressure Changes During Forced Drainage of the Central Nervous System Arch Neurol & Psychiat 16 319 (Sept) 1926. J Exper Med 46 615 (Oct) 1927. Brain 51 244 (June) 1928. Forced Drainage of the Cerebrospinal Fluid Arch Neurol & Psychiat 19 997 (June) 1928.

in three of these. We believe that the use of forced drainage in meningitis merits further trial.

In view of the high mortality, it may be of interest to report briefly our four cases in which recovery took place.

CASE 1—Phyllis M. aged $2\frac{1}{2}$ years, had been well except for a mild cough and cold from four to six weeks earlier. She was taken ill suddenly Aug 21, 1920, with headache, vomiting and fever ranging from 99 to 102 F. Two lumbar punctures were done from August 22 to 26. The spinal fluids were sent to us for examination, and the second showed the Pfeiffer bacillus. August 28 the child was seen by us. She presented a typical picture of meningitis. At this time deafness had developed, 25 cc of spinal fluid was withdrawn and 500 million of a stock influenza vaccine was injected intraspinally. It was not possible to secure the cooperation of the family for regular treatment.

August 31 another lumbar puncture was done, and vaccine was given in a dosage of 1,000 million mixed with antimeningococcus serum, as the smear from the previous fluid had shown coccoid forms which suggested that the meningococcus might also be present. Further studies showed that this fluid as well as the previous ones contained the Pfeiffer bacillus in pure culture. At this point there was some improvement and no further treatment was permitted until September 9, when the child became suddenly worse with a rise of temperature and vomiting. An autogenous vaccine was used as soon as it could be prepared. September 18, the fluid for the first time gave a negative culture, the previous eight fluids having been positive. At this puncture anti-influenza serum (prepared by the research laboratory but not available until this time) was given in addition to the vaccine. The administration of the combined serum and vaccine was repeated September 20 and 22. September 24 and October 2, lumbar puncture was done for relief of pressure, no injection being made. Deafness, which had developed early in the illness and had seemed to clear up, returned about the middle of September. Therefore in this particular case the serum cannot be credited for the disappearance of the organisms and the ultimate recovery of the patient.

CASE 2—M. G., a boy aged 14 years, was taken ill suddenly Jan 28 1923 with headache, vomiting, chills and a fever. Examination, February 3, showed the patient to be acutely ill. The temperature was 103 F, the pulse 130 and the respiration 18. The signs of meningeal irritation were pronounced, showing marked rigidity of the neck, positive Kernig and Brudzinski signs and a positive Oppenheim sign on the left side. A diagnosis of meningococcal meningitis was made.

Lumbar puncture was performed and 30 cc of cloudy fluid was withdrawn under moderately increased pressure. After removal of the fluid 20 cc of antimeningococcus serum was injected intraspinally. The examination of the spinal fluid showed a large increase of cells, practically all polymorphonuclears, a moderate increase in albumin and globulin, and a moderate diminution in the amount of sugar. The smear and culture were both positive for the influenza bacillus.

February 4 there was no change in the clinical picture. Lumbar puncture was performed, 50 cc of cloudy fluid was removed and 20 cc of antimeningococcus serum was administered intraspinally. Examination of the spinal fluid was similar to that of the preceding day, with the exception that organisms were found on smear but not on culture.

February 5 the patient's general condition was somewhat worse and the temperature mounted to 105 F. Spinal tap yielded 35 cc of purulent fluid which showed a marked increase in protein and marked diminution in the sugar content. Organisms were found both on smear and on culture. Twenty cubic centimeters of antimeningococcus serum was again injected intrathecally.

February 6 the spinal fluid showed absence of sugar and the presence of organisms on smear but not on culture. The patient again received 20 cc of antimeningococcus serum.

February 7 there was an improvement in the clinical picture. The spinal fluid showed a moderate amount of sugar and no organisms were found either on smear or on culture. The intraspinal injection of antimeningococcus serum was repeated.

February 9 the patient continued to improve. The spinal fluid was slightly hazy and showed a little increase in protein and a decided rise in the sugar content. The smear and culture remained negative for organisms.

February 10 the child's clinical condition was somewhat worse again. The spinal fluid was again slightly turbid and showed the presence of organisms on smear but not on culture. Twenty cubic centimeters of antimeningococcus serum was given intraspinally.

February 12 the child continued to have an irregular temperature. The spinal fluid showed no organisms either on smear or on culture. Twenty cubic centimeters of anti-influenza serum was injected intraspinally.

February 14 there was a decided improvement in the clinical picture. The spinal fluid was practically clear and remained negative for organisms. The administration of anti-influenza serum was, however, repeated.

From this time on the child continued to improve. A number of lumbar punctures were performed, yielding each time a practically normal spinal fluid. Twenty cubic centimeters of anti-influenza serum was injected intraspinally on February 16 and again on February 18.

February 20 the temperature fell to normal and the patient was free from any signs or symptoms. Recovery was complete.

Following the first four lumbar punctures and the intraspinal injection of antimeningococcus serum there was a definite improvement in the clinical picture, with disappearance of organisms from the spinal fluid. For three days the improvement progressed satisfactorily. The following day, however, organisms reappeared in the spinal fluid. A decided improvement followed the next spinal tap and the intraspinal injection of one dose of antimeningococcus serum. It is to be noted, therefore, that the patient was well on his way toward recovery and the spinal fluid was sterile before the use of anti-influenza serum was begun.

CASE 3¹⁶—T. D., a man aged 28, admitted to Bellevue Hospital Nov 9, 1931, complained of severe headache, vomiting and pain over the back and in the lower extremities. The onset of these symptoms was rather sudden, six days prior to admission to the hospital. There was also deafness from the second day of illness. A few days before the onset of the present illness examination showed the usual signs of meningeal irritation. The temperature was only 100 F. The white blood count was 20,000, with 84 per cent polymorphonuclears. A lumbar puncture was done and 25 cc of cloudy spinal fluid under increased pressure was obtained. On examination, the spinal fluid showed a large increase in cells, mostly polymorphonuclears, marked increase in protein, and absence of sugar. No organisms were found either on smear or on culture. After removal of the fluid, 20 cc of antimeningococcus serum was injected intraspinally.

November 10 the spinal tap yielded 25 cc of cloudy fluid which was positive for the influenza bacillus both on smear and on culture. The intraspinal injection of antimeningococcus serum was repeated. The spinal fluids obtained on November 11 and 12 showed the presence of organisms on smear and culture. Antimeningococcus serum was administered after each puncture.

November 13 the spinal fluid was still cloudy but had a normal sugar content and was negative for organisms both by smear and by culture. Twenty cubic centimeters of anti-influenza serum was injected intraspinally at this time.

The spinal fluids obtained on November 14 and 15 remained negative for organisms. Anti-influenza serum was, however, administered after removal of the fluid in each instance.

November 16 there was marked improvement in the clinical condition. A spinal tap was performed but no serum was given. The spinal fluid remained negative for organisms. Several blood cultures taken during the course of the disease

¹⁶ For the privilege of reporting this case we are indebted to Dr. Alexander Lambert, director, Fourth Medical Division, Bellevue Hospital.

were now reported as negative. A roentgenogram of the skull showed a fissure fracture of the parietal and temporal bones on the left side.

From this time on the patient continued to show progressive improvement. Several more spinal taps were done for relief of pressure. On examination, these fluids were practically normal. With the exception of deafness in the left ear and moderate neuritic pains in the legs, he made a good recovery. He was discharged from the hospital, December 12.

November 13, when the use of anti-influenza serum was started, the spinal fluid had already become sterile and had a normal sugar content. This improvement followed the performance of four lumbar punctures and the intraspinal administration of antimeningococcus serum after each spinal tap. The recovery cannot, therefore, be credited, at least in any great measure, to the use of specific serum.

CASE 4—William M., aged 38, seen, July 21, 1932, had been admitted to the hospital, May 22, 1932, suffering from a severe injury to the head. A diagnosis of fracture of the skull was made clinically but was not confirmed by x-rays. May 22 a lumbar puncture was done, revealing a bloody spinal fluid. The blood count showed 23,000 leukocytes with 86 per cent polymorphonuclears. June 23 there was severe headache, vomiting and a temperature of 104 F., with other signs of meningeal irritation. May 25 the second spinal puncture was done. The fluid was practically clear, with a slightly yellowish tinge. There was some increase in protein and a normal sugar. May 27 a third puncture was done, which revealed a cloudy fluid, and antimeningococcus serum was administered. This procedure was repeated twice on the 28th and once on the 29th. On the 30th it was reported that the spinal fluid had yielded influenza bacillus on culture.

During June and up until the latter part of July, the patient's condition remained about the same. He continued to have a fever and was irrational much of the time. The signs of meningeal irritation persisted. Lumbar punctures were done from time to time. The spinal fluid withdrawn on July 8 still showed organisms. July 21, 20 cc of anti-influenza serum was administered intraspinally. The following day there was a severe serum reaction. No more serum was given. As the serum reaction subsided, the patient appeared much improved. His mentality entirely cleared and he was discharged, August 28, completely recovered.

It is difficult to attribute the favorable outcome to a single dose of anti-influenza serum. It is more likely that the repeated spinal drainage was the important factor in this patient's recovery.

SUMMARY

1 We have correlated certain data in regard to 111 cases of influenza bacillus meningitis under our observation.

2 Influenza bacillus meningitis is essentially a disease of young children.

3 The evidence points to the fact that influenza bacillus meningitis is usually a primary disease and that it is caused by strains of influenza bacilli that tend to fall in one group.

4 The pathologic examination usually shows severe toxic changes in the viscera. There is no particular tendency to the development of adhesions in the meninges or to the formation of abscesses in the brain.

5 In the thirty-five cases in which recoveries have been reported, four have been under our observation.

6 At present there is no adequate method of treatment. Further research should be done toward the development of a more potent serum with high antitoxic as well as antibacterial properties. Serum may be given early intravenously as well as intraspinally.

Foot of East Sixteenth Street

GRANULOCYTOPENIA

REPORT OF TWO CASES

PAULINE ZINNINGER, MD

CANTON, OHIO

It has long been appreciated that a marked decrease in the white blood cell count in the presence of acute infection is an unfavorable prognostic sign. It is only during recent years, however, that granulocytopenia has been recognized as a definite clinical entity. The two cases of this condition reported here presented several unusual features. Both patients were middle-aged women, but the interesting thing is that they were sisters, living in the same household, the recurrence in one and the single attack in the other occurring within about two months. Also, contrary to the usual textbook description, there was practically no angina, but rather there were numerous necrotic lesions in the skin and subcutaneous tissues. Another remarkable observation was that during her second attack patient 1 lived for at least twenty-four days without any granular cells, except a few myeloblasts, and then had a complete remission of the blood picture, although she finally died of sepsis.

Since the cause of this condition is not known, one cannot say which points in the family history are relevant and which not. Several facts in the family history of these patients may be recorded. The youngest sister in the family died at the age of 32 of a severe and generalized arthritis deformans. The only brother was epileptic and died in an institution at the age of 35. The oldest sister is living, aged 66. Patient 1 had scarlet fever with nephritis at 13 years and a hysterectomy for uterine fibroids at 45. Patient 2 had a long-standing bony ankylosis of the right hip, an arthritic deformity.

REPORT OF CASES

CASE 1—*First Attack*—Miss L. M., aged 63, short and rather obese, had a past history that was uneventful until the time shortly preceding the first attack of granulocytopenia. In December 1931, she had a fairly severe attack of herpes zoster and during the next two months a mild infection of the accessory nasal sinuses. These conditions seemed to clear up satisfactorily.

The present illness began rather indefinitely during the middle of April, 1932. The chief complaint was extreme fatigability in a woman who had always been very active. April 24, the patient fainted and was put to bed. The throat was very slightly reddened, the temperature was slightly elevated, and a tentative diagnosis of influenza was made. April 26 a blood count showed the leukocytes to number only 250 per cubic millimeter, with no granular cells to be seen on a stained smear. It was noted then that the patient had a number of small necrotic areas on the fingers which looked like abscesses but contained no pus. She was placed in a hospital, and on April 27 the blood count was as follows: hemoglobin (Newcomer), 75 per cent; red blood cells, 4,579,000; white blood cells, 350; lymphocytes, 100 per cent. She was given one treatment of roentgen exposure to the long bones and on April 28 leukocyte extract was started. This was given from two to four doses of 10 cc each day for six days. Later some pentnucleotide was obtained, but only a few doses were given, as the blood picture was improving. The return of immature granular cells began on the fifth day of treatment with leukocyte extract, a fact which was taken as evidence that it was the result of the therapy and not a spontaneous remission. The white cell count rose rapidly to a maximum of 31,000 per cubic millimeter in the next few days. The granular cells appeared first as myeloblasts and progressed to maturity through the stages of the myelocyte, the unsegmented juvenile form and, finally, the

mature segmented polymorphonuclear neutrophil. The details of the blood studies are shown in table 1.

During the first week of illness the patient was irrational and at times stuporous, had a high temperature and seemed very gravely ill. An area of superficial gangrene appeared in the right anterior axillary region and there developed a thrombosis of the venous channels of the right arm. After the

with a normal differential count. The patient seemed to be as well as before her illness.

Second Attack—About three weeks after the death of her sister, patient 2, and almost exactly one year after the initial attack, the patient had a recurrence. She was quite well, both subjectively and objectively April 13, 1933, but the next day complained that several small cuts and abrasions on her fingers

granular cells returned to the blood stream pus appeared in all the necrotic areas and a large slough occurred in the right axillary region. The resulting sinus finally healed after about six weeks. The temperature became normal about May 6 and remained so except for occasional insignificant rises in spite of a unilateral parotitis which developed on May 8. The patient became suddenly quite rational May 10 and although convalescence was slow, it eventually ended in what seemed a complete recovery by late summer. Occasional blood counts were made throughout the following year and the leukocytes always numbered between 5,000 and 7,000 per cubic millimeter.

were not healing properly and were somewhat painful. She also felt rather tired and had no appetite. A leukocyte count was made immediately and showed only 2,500 cells per cubic millimeter, with lymphocytes 100 per cent. Pentnucleotide was started at once, 10 cc being injected intramuscularly twice a day for five days and then once a day for several more doses. Ampoules solution liver extract No. 343 2 cc a day for four days was also given into the muscle. The patient was nauseated and uncomfortable for a short time after each injection. As there was no improvement in the blood picture, leukocyte extract was given for the next three days. April 20, two myelo-

blasts were seen in counting 100 white cells, and a few of these immature forms were seen in all subsequent smears made during the following two weeks, but there was no evidence of any tendency to maturation of these early granular cells.

Until April 21 the patient was fairly well except for weakness, her appetite was quite good, she had very little fever, and there was no soreness nor redness of the throat. A number of indurated, red areas developed in the skin, one at the mucocutaneous border of the right nostril, one in the left axillary region and many smaller ones on the body and arms. There was no pus formation in any of these, but a smear made of the secretion obtained from one lesion showed great masses of bacteria which in morphology and arrangement looked like staphylococci. April 21 the patient began to be quite sick, and on April 23 there was collapse, a fever of 103 F, auricular fibrillation, and rales at the bases of the lungs. The cardiac irregularity responded very well to digitalis therapy, but the signs in the chest persisted for some time. There was dyspnea and evidence of a pneumonic process in the right lung. The patient was irrational most of the time although she sometimes responded fairly well to questions.

The various skin lesions seemed to shrink and dry for a few days, but no pus developed and they did not heal. The prognosis was regarded as very poor. May 10 the patient was given 10 units of addisin, kindly furnished by Dr. Roger Morris of Cincinnati, and on May 3 an additional dose of 10 units. There was no change in the blood smears during the next three days except for the appearance of from 1 to 2 per cent monocytes. No count nor smear was made, May 7, but on May 8 there was a most surprising change in the blood picture. The smear showed segmented polymorphonuclears, 6 per cent unsegmented polymorphonuclears, 32 per cent, myelocytes 21 per cent, myeloblasts, 1 per cent, lymphocytes, 35 per cent and monocytes, 5 per cent. After this the leukocyte count increased rapidly, reaching at one time 36,300 per cubic millimeter, and maturation of the granular cells progressed steadily. The general condition of the patient did not change much, except for the fact that the indurated areas in the skin and subcutaneous tissues developed into abscesses that were characterized by collections of large amounts of pus with very little induration or inflammatory reaction around them. This was interpreted as evidence that the infection was blood borne. There was also present for some days a frequent, harassing cough productive of fairly large quantities of purulent sputum, so that the presence of a lung abscess was suspected. The abscesses in the skin were incised and evacuated as they became fluctuant, but new ones continued to form. There was a large one in the right groin, following later by a thrombophlebitis of the right femoral vein. During the last week of life fluctuation was detected in the lower part of the right thigh and an incision was made, through which about 500 cc of pus was evacuated.

Throughout the latter half of the illness the patient had a fever of from 100 to 103 F practically every day, she was more or less irrational or comatose most of the time, and, although the total leukocyte count and the differential formula were now quite in keeping with her condition, all hope for her recovery was abandoned. Death occurred June 15, after an illness of two months. Table 2 shows the detailed blood studies.

Pathologic Examination—An autopsy was performed about four hours after death, the body having been already embalmed. A midline incision was made through a thick panniculus of fat, and the breastplate was laid back.

The heart and pericardium were not remarkable.

There was a collection of pus along the intercostal space between the second and third ribs on the right and an adhesion of the right upper lung to the chest wall. On the left the parietal pleura was densely adherent to the parietal pericardium from the level of the fourth rib down. The lower left lobe was adherent to the chest wall. There was one abscess about 4 cm in diameter, and several smaller ones in the right upper lobe. Multiple small abscesses were scattered throughout the left lung.

The spleen was bound by adhesions to the omentum diaphragm and stomach. It was moderately enlarged weighing

312 Gm, and the pulp was rather friable. On section, several abscesses about 4 cm in diameter were seen.

The gallbladder and liver were not remarkable, aside from some fibrosis and perihepatitis.

The kidneys were small but appeared normal in structure. There was a perinephric abscess at the superior pole of the left kidney.

There was an organized blood clot, and some purulent exudate in the right femoral vein. In the right thigh was found a large abscess cavity, about 10 cm by 6 cm, around the lower end of the femur. The bone marrow of the femur was redder than normal.

Microscopic examination of the lung tissue showed areas of necrosis with some inflammatory reaction in the periphery. Many alveoli were filled with mucus and exudate.

Sections of the spleen showed marked congestion. The malpighian corpuscles could not be distinguished. The infiltrating cells were largely mononuclear, but some showed polymorphic nuclei.

In the kidneys there was considerable amount of destruction of the tubular epithelium, congestion of the glomeruli, and fibrosis of the interstitial tissue.

The gallbladder was normal. The liver tissue showed fibrotic changes and large numbers of round cells in the interlobular spaces and around the vascular structures.

Smears of bone marrow, taken from the lower end of the femur and sections of decalcified bone, taken from the sternum showed a very active regeneration of the marrow, with many granular cells present.

CASE 2—Miss A. M., aged 56, had had an arthritic deformity of the right hip and some deformity of the fingers. She had had crops of furuncles at various times in the past. Her illness started during the middle of March 1933 with what appeared to be a number of furuncles on the neck, hands and arms. These she treated herself, using home remedies. On March 21 she suddenly became very weak and sick, and it was noted then that the lesions in the skin were not abscesses but red, indurated nodules having necrotic centers. There were no lesions of any mucous surfaces. A blood count was made which showed a leukocyte count of 477 per cubic millimeter with no granular cells to be seen in the stained smear. Pent nucleotide was started at once, 10 cc being injected into the muscle morning and evening for a total of seven doses. The patient grew steadily worse, lapsed into coma, and died on the evening of March 24 before there was time for any regeneration of the blood. A smear made on the day of death showed only lymphocytes.

COMMENT

The points that were considered to be of particular interest in the cases reported may be summarized briefly. The absence of angina and the presence of skin lesions are, of course, not unique, an increasing number of such instances are being reported. The fact that two sisters should react in the same atypical way might, however, appear to be of significance to those students of the disease who are interested in determining its etiology. In this connection it may be stated that both these patients had been edentulous for many years, since a surprising number of cases have been reported as following the extraction of a tooth. Dennis¹ concludes that pyogenic bacteria may cause granulocytopenia under certain conditions of encapsulation. In the two cases here reported no known focus of infection was present, and none was disclosed at autopsy in case 1. The skin lesions were looked on as distinctly secondary to the lack of granulocytes.

The extremely low leukocyte counts followed by remission are interesting although comparably low counts are now being reported, also with recovery, following treatment.² I have seen no reports in which

¹ Dennis, E. W. Cited in *Experimental Agranulocytic Angina*, editorial J. A. M. A. 101: 368 (July 29) 1933.

the patient lived for so long a time without demonstrable granulocytes in the circulating blood, as in case 1 during the second attack. For at least twenty-four days there was present only a very low percentage of myeloblasts a fact that also demonstrates the "maturation arrest" stressed by Fitz-Hugh and Krumbhaar.¹ The satisfactory response in case 1 to leukocyte extract in the first attack, and to addisin after pentnucleotide and leukocyte extract seemed to fail, in the second attack, are also points worthy of note.

HODGKIN'S DISEASE OCCURRING SIMULTANEOUSLY IN TWO BROTHERS

G J McHEFFEY, MD

AND

R F PETERSON, MD

BUTTE, MONT

The two most common diseases that cause a progressive glandular enlargement in youth are tuberculosis and Hodgkin's disease. Consequently the diagnosis often lies between these two. These conditions may resemble each other so closely in the early stages of glandular enlargement that the clinical diagnosis between them is almost impossible. Furthermore there is no absolute evidence of inherited tendencies in Hodgkin's disease or of direct contagion, and the occurrence of more than one case in a single family is of the greatest rarity. The opposite is true of tuberculosis. In the literature are found only a few reports of Hodgkin's disease in more than one member of a family. In 1911 Ziegler¹ stated that there were no recorded cases of the disease in parent and child and that no hereditary predisposition had been demonstrated. Cases in twins have been reported by Peacock² and Senator.¹ Degen¹ saw a brother and sister with the disease. Braum,¹ in 1912, reported three cases of malignant disease of lymph glands in a woman and her two brothers. Arkin,³ in 1926, reported three cases of mediastinal lymphogranuloma in one family all men, a father, his son, and his nephew (the father's brother's son). In reporting these cases, Arkin states that it may be assumed that the three male members of the family possessed a familial predisposition to mediastinal Hodgkin's disease. Keeping these few introductory remarks in mind, we report two cases of Hodgkin's disease occurring almost simultaneously in two brothers, aged 11 and 13, respectively. As the clinical features and course of both of these cases were almost identical, reporting the case history of one will report that of the other except for a few minor details which will be mentioned during the course of the narrative.

REPORT OF CASES

G S aged 11 and P S aged 13 years, American born schoolboys of Swedish extraction were in good health until the onset of their present illness. Both boys had had measles and mumps, but aside from this the past history was negative.

The father is living and well. The mother died eight years ago of bronchopneumonia. According to the father there were no tumor masses or evidences of glandular enlargement in the mother. Two brothers are living and well, one brother died

at the age of 2 weeks of an unknown cause. Four sisters are living and well, one sister died in infancy of an unknown cause.

In January, 1931, the father of the two patients noticed a slight swelling on the right side of the neck of the younger of the boys, this swelling was situated over the right posterior auricular and upper right posterior cervical area, there was no soreness or tenderness of this mass, but it appeared to be getting larger from day to day. One week later, the father noticed the appearance of a similar swelling of the neck of the older of the two boys. The onset and course of the latter swelling was similar to that of the younger brother except that the mass was situated over the left side of the neck. The father took the boys to a local physician who naturally suspected tuberculous lymph glands and advised the boys to go to a sanatorium for tuberculosis. The boys were in such an institution for thirteen months and, while there the lymph glands in the neck became so large that they were unable to turn their heads. They lost a few pounds in weight but had no night sweats or chills. Occasionally they would elicit a dry cough but had no dyspnea nor palpitation of the heart. On exertion they both complained of a slight retrosternal pain. Repeated Mantoux tests at the sanatorium were negative and the diagnosis of tuberculosis was never verified. During their stay at the sanatorium they were treated with ultraviolet rays. Shortly before they left the sanatorium, biopsies of cervical tumor masses were made and the pathologic diagnosis was that of lymphoma.

In June 1932, the two boys came under our observation. At that time physical examination revealed the following picture. Both boys appeared to be well nourished and well developed, there was a very slight pallor of the skin and of the mucous membranes. The skeletal system was normal. On the right side of the neck of the younger boy were various sized multinodular masses involving the right cervical and posterior auricular chains of lymph glands, extending from the lower posterior aspect of the ear down to the root of the neck, there was no adherence of the masses to the skin and no puckered scars of the skin or draining sinuses were present. On palpation the tumors were not soft or fluctuant but had a resilient firm "art gum" feel. Aside from the glandular enlargement of the right side of the neck there were no other palpable lymph glands. The older boy showed the same lymph glandular change as the younger brother the only difference being that the left side of the neck was involved instead of the right. The teeth were in fair condition and the tonsils small and

Blood Count

	Younger Boy	Older Boy
Hemoglobin	71% (Dare)	64% (Dare)
Red blood cells	4,400,000	4,840,000
White blood cells	7,700	11,000
Neutrophils	72%	72%
Small lymphocytes	13%	12%
Large lymphocytes	10%	8%
Eosinophils	5%	8%

atrophic. Examinations of the lungs were negative. The heart, in both boys showed a soft hemic murmur at the apex. Pulses were regular but rapid. In each case the spleen was slightly palpable. Otherwise examination of the abdomen was negative. The extremities were normal. Examination of the nervous system revealed normal conditions. The temperatures of the two boys were 103.2 and 103.4 F (rectal) respectively. Their weights were 79 pounds (35.8 Kg) and 120 pounds (54.4 Kg), respectively.

Examinations of the urines were negative. Results of the blood count are given in the accompanying table. Shortly before death the hemoglobin dropped to 8 per cent (Dare) and the red blood cells in each case were less than 1,000,000. The blood pictures for both boys showed a slight anisocytosis, a slight poikilocytosis, no normoblasts or megaloblasts, no stippling and no abnormal leukocytes. The Arnett index was normal. There was moderate hypochromasia.³

Roentgen examinations of the lungs in both cases were negative.

³ Arkin Aaron. Familial Mediastinal Lymphogranuloma. Am J M Sc 171: 669 (Mar.) 1926.

A biopsy was performed on both boys and a diagnosis of Hodgkin's disease was made on both specimens

Both patients were given palliative high voltage roentgen therapy with the usual results, characterized by a rapid recession in size of the tumor masses but followed by an equally rapid recurrence in the same areas. Symptomatically neither patient showed any improvement but continued to decline rather rapidly from month to month. The oldest boy would manifest a considerable reaction following each roentgen treatment, characterized by chills, high fever and marked weakness. Consequently he did not receive as much roentgen therapy as did his younger brother.

During the course of their illnesses each patient had a daily afternoon rise in temperature and both became progressively weaker, more cachectic and more anemic. One month before their respective deaths, each one showed marked edema of the face, eyelids and ankles, marked pallor (pale-blue-white) to the skin, deep bluish lips, hydrothorax, hydropericardium, loud blowing systolic murmur at the apex, ascites, an enormously enlarged spleen, generalized lymph adenopathy, hemorrhages from the nose, and petechiae. The petechial rash in both boys occurred first over the sternum and then appeared over the legs, arms and trunk, in the order named. The younger of the two brothers died in January, 1933, two years after the onset of his ailment, and the older of the two brothers died in March, 1933, two years and two months after the onset. Permission for postmortem examination in both cases was granted.

An autopsy was performed on P S, March 27. The body was well developed but markedly emaciated. The skin showed an icterus of 2+ on a basis of 4. The anterior aspects of the chest, abdomen and neck were covered with innumerable petechiae. There were also a moderate number of petechiae over the forearms, knees and feet. The cervical lymph nodes

were all moderately enlarged on the right and markedly enlarged on the left, especially the lower halves of the anterior and posterior cervical groups. They were of a firm, rubbery consistency. The axillary and inguinal nodes were barely palpable. Subcutaneous fat was nearly all absent. The abdominal cavity contained about 750 cc of clear amber fluid. The peritoneal surfaces were smooth and glistening. The liver was 4 cm below the xiphoid process and 3 cm below the rib margin at the right anterior axillary line. The liver weighed 2,275 Gm and was very pale, there were a few yellowish-white nodules through the liver substance, varying from 0.5 to 5 cm in diameter. The gallbladder was dilated to 13 cm in length and 5 cm in diameter at the largest dimensions, it was filled with pale green bile. There was a white nodule the size and shape of an almond in the proximal anterior part of the gallbladder wall. There was an irregular mass of large lymph nodes, together the size of a fist, about the duodenum and obstructing the common duct. All the abdominal lymph nodes, including the mesenteric and the preaortic, were enlarged to from 1 to 5 cm in diameter. The spleen was enlarged to 900 Gm. On both external and cut surfaces were many firm yellowish-white areas from 0.25 to 2 cm in diameter. The gastro-intestinal

Fig 1—P S aged 13 years seventeen months after onset

tract was normal throughout. The left kidney weighed 300 Gm, the right, 270 Gm. They were pale and flabby, with the markings decreased in prominence. The capsules stripped easily. The pancreas, bladder and suprarenals were grossly normal. The left pleural cavity contained about 300 cc of amber fluid and the right about 100 cc. Both lungs showed moderate posterior dependent congestion but were otherwise normal. The mediastinum contained several moderately enlarged nodes. The pericardiac cavity contained about 100 cc of dark amber fluid. The heart was normal throughout. The blood was very thin and pale, showing no postmortem clotting.

Microscopically, the lymph nodes showed fairly cellular Hodgkin's disease with a moderate number of eosinophils, Dorothy Reed cells, and many areas of necrosis. The spleen involvement was typical of Hodgkin's disease. The liver showed nodules of Hodgkin's disease with surrounding pressure atrophy.

The other organs showed no pathologic changes of importance. An autopsy was performed on G S, January 21. The conditions found were almost identical with those recorded for the older brother, with the following exceptions. The external lymph nodes were largest on the right rather than

on the left side. There was no involvement of the liver and no large mass of nodes obstructing the common duct as in the former, though the abdominal nodes were all markedly enlarged. The nodes were all somewhat firmer than those of the older boy.

Microscopic examination revealed extreme fibrosis of all the lymph nodes but especially so of the cervicals. The spleen involvement, though grossly similar, also showed more fibrous tissue than was shown in the other autopsy.

It will be remembered from the history that the younger boy had received more roentgen treatment than the older, and this may be a causative factor in the increased fibrosis revealed in the microscopic picture.

Fig 2—G S aged 11 years seventeen months after onset

Microscopic examination revealed extreme fibrosis of all the lymph nodes but especially so of the cervicals. The spleen involvement, though grossly similar, also showed more fibrous tissue than was shown in the other autopsy.

It will be remembered from the history that the younger boy had received more roentgen treatment than the older, and this may be a causative factor in the increased fibrosis revealed in the microscopic picture.

CONCLUSIONS

- 1 Two cases of Hodgkin's disease in brothers, aged 11 and 13 years, respectively, occurred simultaneously.
- 2 The onset was a week apart and death occurred about two years later, two months apart.
- 3 These cases demonstrate the value of an early biopsy, since tuberculosis was naturally the clinical diagnosis.
- 4 There is no evidence of Hodgkin's disease in any of the family history.
- 5 Our conception of Hodgkin's disease is that of a neoplasm rather than that of an infectious granuloma. The simultaneous occurrence of this condition in two brothers does not shake our belief, because these two cases make a total of only twelve cases in five families which we could find reported.

Murray Hospital Clinic.

DINITROPHENOL

ITS THERAPEUTIC AND TOXIC ACTIONS IN CERTAIN
TYPES OF PSYCHOBIOLOGIC UNDERACTIVITY

JULES H. MASSERMAN, M.D.

AND

HARRY GOLDSMITH, M.D.

BALTIMORE

In a recent report, Cutting, Mehrtens and Tainter¹ summarized their experimental and clinical studies of the pharmacologic properties of alpha-dinitrophenol (1-2-4) ($C_6H_3(NO_2)_2OH$) and concluded that

The outstanding actions [of the drug] are sustained increases in metabolism and body temperature, enormous activity of all metabolic functions, and fatal pyrexia with excessive doses. Doses within therapeutic range cause in man significant increases in metabolism without fever, which may be useful in treatment of obesity, hypothyroidism and similar depressed metabolic states.

In a later communication, Tainter, Stockton and Cutting,² reporting on their clinical experience with the use of the drug in the treatment of obesity, stated

The predominant action of dinitrophenol is to stimulate metabolism and heat production. An average loss of weight of between 2 and 3 pounds weekly was produced by an average daily dose of 0.3 Gm (5 grains) of the sodium dinitrophenol, in capsules taken with meals. The drug has been administered to individual patients by us continuously for as long as four months without demonstrable evidences of cumulative or toxic effects. A suitable regimen of dinitrophenol medication for adults would appear to be an initial daily dose of 100 mg of the sodium salt orally, taken with meals, with an increase at weekly intervals until a dose is established that causes a loss of body weight of between 2 and 3 pounds weekly or too marked or unpleasant symptoms of warmth and sweating.

With the pharmacologic action and safe dosage of dinitrophenol thus tentatively established, it appeared of importance to determine whether the drug would be efficacious in increasing the subnormal metabolic rates often found in dull, depressed, listless, apathetic psychiatric patients³ and thus prove of benefit, in a psychobiologic sense, in the empirical treatment of these patients. It is our purpose in this report to outline our experiences with the use of sodium dinitrophenol in eighteen such cases over a period of four months.

MATERIAL AND METHOD

Patients were selected who were between 18 and 40 years of age and free of gross organic disease. The finer nosologic differentiations were disregarded, the psychiatric criterion for inclusion in the group being a change within the previous year from an outwardly satisfactory and adaptable mental state to one characterized by listlessness, indifference, mild depression and otiose lethargy. Oxygen consumption tests were run on each patient before treatment was begun and repeated until a reading—generally the lowest—was obtained that seemed most closely to approximate the

true basal metabolic rate in each case. The patient was then given 60 mg (1 grain) of sodium dinitrophenol per day, and the dose usually increased 60 mg every third day until a maximum of 5 mg per kilogram in divided doses with meals twice a day was reached or until adverse symptomatology appeared to contraindicate further treatment. Routine blood counts and urine examinations were done twice a week and the oxygen consumption rates rechecked at approximately weekly intervals. In addition, the nonprotein nitrogen of the blood, and the icteric index and Van den Bergh reactions were determined when indicated. Each patient's temperature, pulse rate and respiratory rate were observed at eight half-hourly intervals after each dose during the first week and three times a day thereafter, and records of the weight, symptomatology, spontaneous activity and mental state were made twice a week throughout the treatment. Medication in each case was continued for three months, after which the physical, mental and laboratory examinations were repeated and any definite changes in the case summarized.

PSYCHOBIOLOGIC EFFECTS OF DINITRO-
PHENOL MEDICATION

Physiologic—With the exception of five cases, all patients were kept on a regular dosage throughout the three months study save for monthly rest intervals of one week inserted as control periods. The effects of sodium dinitrophenol on the thirteen patients given this full treatment may be summarized as follows. No gastro-intestinal or genito-urinary disturbances fairly attributable to the drug were observed in any instance. The pulse rate under full dosage rose from four to twenty-two beats per minute, but analysis of successive blood pressure readings in the thirteen cases showed no significant deviations from the individual norm. No persistent changes in blood cytology or urinary constituents were noted. In five cases a yellowish discoloration of the sclerae and skin was observed under full dosage, but the icteric index in each instance (when done so as to eliminate the seroanthochromic effect of the drug itself⁴) was normal.

Metabolic Rate The oxygen consumption rate of our patients rose from a pretreatment control mean of -69 ± 1.54 to 260 ± 2.95 under maximal dosage; the mean rise in metabolic rate being therefore 32.9 ± 3.31 and ranging from $+8$ to $+52$ in individual patients. Within a week after cessation of treatment, the mean metabolic rate in the thirteen cases had fallen to -1.8 ± 2.28 , a rate not significantly different from the control pretreatment mean, although two cases showed some persistent elevation of metabolic rate for fifteen days following treatment.

Weight The weight loss during medication varied considerably. Patients whose metabolic rate was elevated less than 15 per cent (three patients) either suffered little or no loss of weight or actually gained slightly as the result of an apparently increased appetite, other patients, excluding the patient who died, lost from one-half to approximately 2 pounds (from 227 to 917 Gm) a week. The grand mean rate of loss in our series was $9\frac{1}{100}$ pound (426 Gm) a week.

Psychologic—The effects of the dinitrophenol medication on the mental status of our patients varied widely. A study of the behavior charts and the successive mental examinations made on each patient revealed that in eight instances no psychologic change

4 Mean \pm its probable error.

could definitely be attributed to the pharmacologic action of the drug, whereas in four cases the periods of medication were characterized by a decrease in spontaneous interest and activity and a deepening of the mental and physical indolence into lethargy and torpor. Conversely, maximal administration of the drug in six other patients was accompanied by a lightening of the mood, progressive clearing of the sensorium and definite increase in spontaneous awareness and activity, the evidences of improvement being checked by more or less well marked retrogressions during the first and second seven-day rest periods. Of the six patients, three manifested a tendency to remission toward their former mental state when the drug was finally discontinued, whereas the remaining three have maintained their initial improvement to date.

Toxic—Our series includes one death.⁵

A M., a Negress aged 31, weighing 130 Kg (288 pounds), on physical examination was normal except for an enormous panniculus adiposus. The blood pressure was 162 systolic, 108 diastolic. Routine blood, urine and spinal fluid examinations were negative. Wassermann tests of the blood and spinal fluid were negative. The patient was physically lazy, slothful and inert, mentally retarded, sluggish and apathetic. The intelligence quotient was 58. The basal metabolic rate Sept. 16, 1933 was -14 , September 17 it was -19 . Dinitrophenol medication 0.12 Gm with the noon meal, was begun September 19 and increased 0.06 Gm every day until by September 24, the patient received 0.42 Gm in divided doses daily. The temperature, pulse and respiratory rate taken every half hour for four hours after each dose showed no significant deviations from normal. September 26, the weight was 284 pounds (128 Kg), the basal metabolic rate $+15$. The patient had an increased appetite and was slightly more active, no other effects were apparent. The dosage increased to 0.3 Gm twice a day. October 1 the weight was 281 pounds (127 Kg), the basal metabolic rate was 19. The pulse ranged between 82 and 98. The rectal temperature readings every two hours were normal. There were no further changes in the behavior. October 2, the patient complained occasionally of difficulty in breathing and appeared confused and torpid. The pulse ranged from 96 to 110, the blood pressure was 142 systolic, 88 diastolic. Physical examination otherwise was negative.

Dinitrophenol was discontinued. October 3, the patient was stuporous and dyspneic, respirations ranged from 24 to 28, the pulse from 92 to 120, the blood pressure was 144 systolic, 68 diastolic. The cytology of the blood was normal, the non-protein nitrogen of the blood was 35 mg per hundred cubic centimeters. The icteric index was 5.5, and the carbon dioxide combining power of the blood was 30. The urine was clear. On two occasions 1000 cc of 10 per cent dextrose with 40 units of insulin was administered by vein without apparent improvement. Epinephrine, caffeine and atropine were given as seemed indicated. The highest rectal temperature was 100.4 F at noon, pulse 120. October 4 the patient was comatose, incontinent and cyanotic. Coarse rales were heard in the lung bases. The pulse ranged from 118 to 148, the respiratory rate, from 28 to 48. The highest rectal temperature was 102, just before death at which time the blood pressure had fallen to 36/0. The patient grew progressively weaker despite all supportive measures and died at 10 p.m.

At autopsy the only gross abnormal observations were obesity, fibrous pelvic adhesions, slight scarring of the tricuspid and mitral valves, hypertrophy of the right ventricle and small scattered fatty deposits in the aorta. There were no evidences of other gross lesions in any organ or of terminal pulmonary infection or cardiac failure. Unfortunately because of the patient's indigence the autopsy was necessarily delayed four days so that exact interpretations of the microscopic sections of the viscera were rendered impossible by tissue autolysis. Sections of the central nervous system showed no definite pathologic changes.

Since this case—one of the earliest in our series—presented evidence that dinitrophenol may possess a cumulative toxic activity which is not heralded by excessive sweating, dermatitis or pyrexia¹ but which seems, on the other hand, to be characterized by a fall in the blood pressure, tachycardia, the onset of acidosis and progressive torpor, we naturally stopped administration of the drug to all subsequent patients who, under any dosage, showed an accentuation of their lassitude, a persistent fall in blood pressure, or a pulse rate of over 100 for longer than six hours. Four additional cases showed these symptoms within from six days to three weeks after the beginning of treatment, further therapy was therefore discontinued in these cases. Possibly because the patients with an idiosyncrasy to the drug were thus eliminated, we observed no other unfavorable "side actions"¹ of the drug in the remainder of our series.

COMMENT

While it cannot at present be established that the rate of somatic metabolic activity, even of the central nervous system, furnishes a paradigm for the quantity or quality of psychodynamic energy, it is nevertheless interesting to note that Hoskins^{2b} in a careful experimental and statistical study, showed that the mean oxygen consumption rate in 214 cases of dementia praecox was 88.3 per cent of normal (11.8 per cent coefficient of variation), the rate being most depressed (87.9 per cent) in the sluggish, inactive catatonic group. It is also relevant to note that all our cases were readily classifiable as schizophrenic, hebephrenic or catatonic in type, the alternative possibility of a hypothalamic disturbance being prominent in only five instances. Our data concerning an initially depressed metabolic rate in this type of patient therefore confirm those of Hoskins and, allowing for the small number in our series, do not differ statistically from his.

Our experiences with the pharmacologic properties of sodium dinitrophenol coincide in general with those of its proponents.² The drug undoubtedly stimulates general body metabolism and, by inference, that of the central nervous system. In our series, however, its toxicity in the recommended dosage seemed to be considerably greater than heretofore reported, the primary warning signs of its noxious action being a fall in blood pressure, the onset of acidosis and progressive tachycardia and torpor.

An evaluation of the data at hand with regard to the psychotherapeutic activity of dinitrophenol is difficult, since the element of spontaneous variation cannot be absolutely excluded from so small a series. However, it was felt that lengthy citation of the case records in the present study would be of no additional advantage in forming a fair evaluation of the results obtained, since our judgment as to whether the psychiatric changes observed in an individual patient could or could not be attributed to the medication was predicated not only on a study of his behavior charts and formal mental status records but also on previous experience with each patient and close contact with him during the period of his treatment. One general observation, nevertheless, deserves mention. The six patients in our series who derived benefit from the medication were below the age of 30, and four of them had been suffering from the first occurrence of a retarded-aphathetic state. The problems raised by these observations are at present being studied in a larger series of cases.

⁵ One other death has been reported by J. C. Geiger (J. A. M. A. 101: 1333 [Oct. 21] 1933).

SUMMARY AND CONCLUSIONS

The pharmacologic and psychotherapeutic effects of sodium dinitrophenol were studied in eighteen patients whose psychobiologic status was characterized by sluggishness, passivity and apathy. In therapeutic dosage the drug caused a mean rise of 32.9 ± 3.31 per cent in the rate of oxygen consumption and a mean weight loss of $9\frac{1}{100}$ pound (417 Gm) per week. Toxic effects occurred in five cases and were characterized by a fall in blood pressure, tachycardia, acidosis, progressive stupor, and one death. Indeterminate or adverse psychotherapeutic effects were observed in eight and four cases, respectively, while six patients showed a definite improvement in their mental state apparently attributable to the medication. Dinitrophenol is therefore unpredictably toxic to some patients, but its careful administration may be of empirical benefit in certain types of recent and insecurely established psychobiologic underactivity.

NORMAL SLEEP PATTERN FOR
CHILDRENFACTORS WHICH DERANGE SUCH A PATTERN
(PHYSICAL FACTORS)GLENVILLE GIDDINGS, MD
ATLANTA, GA

Sleep may be defined as a normal temporary loss of consciousness occurring periodically. During sleep the receptivity of the person to sensory stimulation is greatly diminished, but motor activity continues in an apparently automatic manner. There are several approaches to the study of sleep. Of these, the most commonly used in the past have been, first, investigation along the line of sensory response, as an example of which there are the experiments of Kohlschutter¹ and Michelson,² second, from the standpoint of chemistry, principally the work of Pieron,³ and third, the study of motor activity during sleep based on the reported work of Karger,⁴ Renshaw,⁵ Guttman,⁶ Mullin⁷ and Cooperman.⁸ In the present study I have used the latter method of study, namely that of motor activity during sleep. I have adopted this method because I agree with Sherman,⁹ Renshaw⁵ and others that an observer cannot tell with any sufficient degree of accuracy whether a person is awake or asleep at any given instance. I know of no method so far evolved of determining the exact moment at which a person is definitely asleep or at which moment he first awakens. I believe with Johnson and Weigand¹⁰ that an accurate record of all movements made by a person after retiring is the most

accurate index as to the character of that particular person's sleep. I further believe that no healthy person can return to the awakening state from sleep or be awake and remain in dorsal decubitus for more than a very short time without rearranging his position. I assume, therefore, that the depth of sleep is inversely proportional to the amount of sleep movement and I concur with Kohlschutter's¹ observations that the soundest sleep is reached within the first and second hour after retiring. For these reasons, such descriptive terms as "asleep" and "awake" are unsatisfactory, certainly from a standpoint of scientific investigation.

This paper is presented as a study of the sleep of twenty-eight children, aged from 9 to 14 years, equally divided as to sex, over a period of 364 nights. I have records of 8,736 child nights, or 78,624 hours, or 4,717,440 minutes, of sleep. My observations were begun in February, 1932, and may be completed during the present summer. This paper is presented as a preliminary report. In a study of sleep recorded by an instrument of precision, one is at once impressed by the number of variable factors that may disturb sleep. When one studies the various influences, such as noise and quiet, light and darkness and heat and cold, one has mentioned only a few of the factors that enter into the production of, or into the interference with, sleep, many of which are, of course, beyond one's control. In these studies an effort has been made to control these extraneous factors as thoroughly as possible. The sleep laboratory is located miles from a railroad or public thoroughfare, so that noises are reduced to a minimum. All of the children studied had identical beds, springs, mattresses, pillows and bed clothing. Barometric readings were made twice a day at the same hours, changes in temperature were noted by a continuously recording thermometer.

What happens when an individual or a child, goes to sleep? Does he go into a state of suspended animation and remain entirely motionless, or do the voluntary muscles contract in sleep just as the involuntary muscles continue their activity? If a child moves in his sleep does the movement vary from hour to hour and from night to night? Cannot these movements be observed and recorded in a definite sleep pattern for a child? Would this sleep pattern differ in children of the same and opposite sex? Does sound sleep mean quiet sleep? Does a child feel as refreshed after a night in which the sleep movements have been frequent, as when the sleep movements have been infrequent? What are the effects of the emotions on sleep? What is the effect of the various hypnotics on sleep? Are sleep movements affected in disease? What are the effects of the various physical agents on sleep? All of these questions, and many more, seem fit subjects for controlled investigation.

For the first three months of the investigation on sleep the data were obtained by direct visual inspection of the sleepers. Two night nurses were assigned to this duty, they noted any change of position of the children under observation. It seemed best to limit observations to change of position, as many minor movements eluded detection. A form using symbols for the various positions of the body was arranged for this, so that the nurse could rapidly fill in the night's observations and transcribe them the following morning. With this method it early became apparent that only a small part of the picture was being obtained. Therefore I began to use the electrically recording hypnograph.

METHOD AND APPARATUS FOR RECORDING
SLEEP MOVEMENTS

The machine used for recording sleep was originally described by Renshaw⁵ and Weiss in the *Journal of Psychology* in 1926. In brief, the principle involved is as follows: The bed mechanism attached to the bedspring consists of a perpendicular piece of metal containing alternate inserts of bakelite and brass. A small brass wheel travels up and down this piece, which makes or breaks an electric contact with the slightest movement of the person occupying the bed. This contact is conducted through cables into an adjoining room in which is placed the hypnograph itself. The hypnograph consists of a battery of twenty-four stylus pens (one for each bed) which write on a uniformly traveling roll of paper, 8 inches (20.32 cm.) broad. Two colors of ink are used in the pens, one for the male and another for the female subjects. As this paper passes under the pens, it is stamped electrically by a timer at one minute intervals, so that at the end of a night's observations this can be ruled out sixty minutes to the hour and each body movement accurately recorded, minute by minute, for the entire nine hours or 540 minutes that the subject is in bed. As the contacts are made or broken by the bed mechanism, electromagnets on each pen of the hypnograph make offsets from the base line on the record. Beside the hypnograph are relay boxes so arranged that if the circuit through any bed ceases functioning properly, the signal lamp will light and remain burning until the condition is corrected. Thus should a subject leave his bed for any purpose during the night, the relay lamp will at once notify the operator of this fact.

At the beginning of the work each child who was to be studied was given a physical examination and such laboratory tests as urinalysis, complete blood count, blood pressure, electrocardiographic tracing, basal metabolic rate, examination of the stool and the like. At this initial examination all foci of infection that were found were removed. Likewise, the children with organic defects were excluded from this group.

At the end of each night's observations the active minutes that is, any minute during which a sleeper makes any movement are counted hour by hour, and recorded for each of the

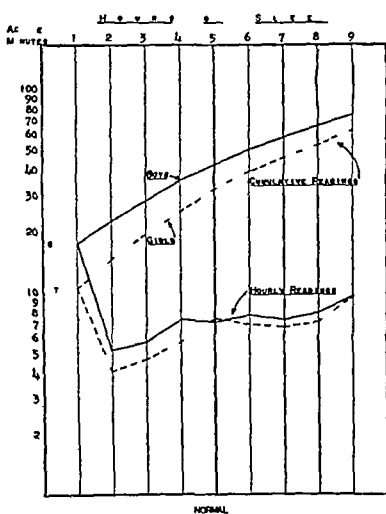

Fig. 13—Curves of sleep of twelve male subjects compared with twelve female subjects

a period of fifteen consecutive nights as registered by the hypnograph.

It is quite apparent that while certain evidence is gotten by observation alone, it is by no means as accurate or complete as when the movements are recorded electrically. For example, to date I have graphic records of about 78,624 hours of sleep, and the highest period I have found of any person sleeping without any body movement is 107 minutes (one hour and forty-seven minutes).

These observations of sleep movements in health are based on a study of 3,240 hours of normal sleep. Except in a very general way no two persons have the same sleep pattern. It is known that the first hour of sleep is the most active hour, and the next most active is the last regular hour of sleep. I can go further than this and say that the most active part of the night is the first thirty minutes after retiring, and the most quiet part is the second thirty to forty-five minutes. For example, if a person is in the habit of retiring at 10 p. m. and

Fig. 14—Effect of warm water and cold water on the sleep pattern. The continuous curve is for normal sleep, the broken curve for sleep after the drinking of warm water, the dotted curve for sleep after the drinking of cold water.

of getting up at 7 a. m., he will show more activity—more sleep movements—between 10 and 11 p. m. and 6 and 7 a. m. than any other two hours of the night. Aside from this, generalities cease, and what is quite normal for one person may be distinctly abnormal for a second person, on the assumption that both are in normal physical condition. This variability of sleep patterns is equally true for males and females.

The graphs are all plotted on ratio paper. The hours of sleep are listed at the top of the graph with a scale showing the active number of minutes to the left of the graph. The lower limb of the graph shows the body movements, hour by hour, of the person under observation, the upper limb of the graph is a summation of the minute movements throughout the night.

Among the twenty-four children studied, the greatest variation in the normal sleep pattern was found in the male subjects. The most active boy studied showed an average of 110 active minutes of sleep during the night, while the most quiet one showed an average of only 53 active minutes, both over a period of fifteen consecutive normal nights. Figure 13 shows fifteen consecutive normal nights of sleep in male subjects as compared with those in twelve female subjects. It is seen that females are sounder sleepers than males, they not only get to sleep more quickly but sleep more quietly throughout the night. This substantiates observations by Ladame.¹¹ His conclusions, however, are based on direct observations, without recording apparatus and therefore are probably not so reliable.

If the entire group of twenty-four children is arbitrarily divided into three groups, based on their activity during sleep, the following facts seem to be true. Suppose the group averaging from fifty to sixty active minutes per night are called "quiet sleepers," the group between sixty-one and eighty-four active minutes per night "average sleepers" and the group between eighty-five and a hundred active minutes per night "restless sleepers." With this division, five children, or 20.8 per cent, will fall in the quiet group, sixteen, or 66.6 per cent, in the average group, and three, or 12.5 per cent, in the restless group. It is interesting to know that the

¹¹ Ladame, C. Du sommeil et de quelques unes de ses modalités chez les aliénés. *Schweiz. Arch. f. Neurol. u. Psychiat.* 13: 371, 1923.

children who were "restless sleepers" will move approximately two and a half times more in the first hour than the children who were "quiet sleepers." Furthermore, it is believed that after getting even a few nights of normal hypnograph records, a child can be definitely rated as to type of sleep. From observations with normal children, sleeping under controlled conditions, it can be stated that a child who is a "quiet sleeper" remains a "quiet sleeper," and that a child who is a "restless sleeper" will remain restless from week to week, month to month and season to season.

I shall present in this report principally the effect on sleep of various physical factors, namely, beverages, food, baths and weather temperature.

THE EFFECT OF CERTAIN BEVERAGES ON SLEEP

It has long been accepted that the drinking of certain beverages on retiring induces sleep. The taking of warm milk on retiring, more especially by neurotic persons, is a time-honored form of therapy. I thought that it might be interesting, therefore, to test the ingestion of warm milk and other beverages on retiring and determine by hypnographic observations just what effect this would have on sleep. This experiment was done on twelve normal children selected because it is believed that in children any psychic factor can be disregarded. Should any changes be noted in the children's sleep, would similar changes have been observed had the child taken cold water, warm water or any one of a number of other beverages? Therefore, in the first experiment, to the series of children mentioned 6 ounces (178 cc) of cold water was given on retiring, and the children were in bed and the lights were out at 8:30 p.m. This was repeated on five consecutive nights. Following this, warm water in a like amount, given at the same time, was repeated for five consecutive nights. From a study of these series it can be seen that the sleep movement was increased in some children, diminished in others and unchanged in the remainder. A typical example is seen in figure 14.

In making an estimate of the significance of the results obtained it seemed wise to adopt the biometric method which is widely used, namely, that of calculating the probable error. In explanation of the meaning of the probable error, it can be stated that it has been practically a universal custom among biometric workers that the difference (or constant) which is smaller than twice its probable error is probably not significant whereas the difference (or constant) which is three or more times its probable error is either "certainly" or at least "almost certainly" significant.¹² In the case of the experi-

ments with warm water the difference in the number of movements before and after the experiments was less than three times the probable error in 83 per cent of the children, was greater in the same percentage of children, and was less than twice the probable error in 83.3 per cent of the children. On nights on which cold water was received, there was decreased activity in 16.7 per cent of the children and an increase in 25 per cent, and in 58.3 per cent of the children there was no effect noted whatsoever. A similar experiment was done with 6 ounces of warm milk given on retiring to twelve normal children on five consecutive nights. From a study of the results obtained it can be seen that the sleep movement was increased in some children, diminished in others and unchanged in the remainder. Comparison of the action of warm water and warm milk is shown in figure 15. From the standpoint of the probable error it was seen that in 41.7 per cent of the children the activity was diminished, movement was increased in 83 per cent, and in 50 per cent there was no change noted whatsoever. A further experiment was done in which twelve normal children received 6 ounces of a cold caffeine-containing beverage on consecutive nights, the beverage containing approximately $\frac{3}{8}$ grain (0.03887 Gm) of caffeine and 20 Gm of sucrose to 6 ounces. Deductions made after estimating the probable error in this series showed that there was less activity in none of the children, in 18.2 per cent of the children there was an increased activity, and in 81.8 per cent there was no effect noted. A concluding experiment using 6 ounces of orangeade containing 20 Gm of sucrose was given to twelve normal children on consecutive nights. Deductions after determining the probable error in this series showed that there was less activity in none of the children and an increased activity in 18.2 per cent, and in 81.8 per cent there was no effect noted whatsoever. Figure 16 shows the comparative sleep patterns after receiving orangeade and cold caffeine-containing beverages as compared with the normal.

It is rather difficult to interpret these results. It seems fair to conclude that warm milk has a definite ability in lessening the number of sleep movements in normal children. Why there is increased sleep movement in the series receiving cold water greater than in the series receiving orangeade and cold caffeine-containing beverage is not understood. It would seem fair to conclude that if the restlessness was due to an increase of urination as a result of the intake of fluid on retiring, it should be the same in both instances, as the amount of fluid was identical in each of the five series. These observations are based on a series of sixty child nights, and it is possible that obtaining a

larger number of observations might change these figures to some degree

THE EFFECT OF A HEAVY MEAL ON A CHILD'S SLEEP

This experiment was done on a series of twenty-four children in order to determine what might be the effect on sleep of the taking of a heavy evening meal. Dinner was served at 6 30 p. m. and the children retired at the usual hour of 8 30 p. m. The meal was made up of comparatively plain food of considerable variety, and the children were allowed to eat as much as they wished, which in all instances was a considerable amount. The meals were not given on consecutive nights, but at intervals and consisted of a fruit course, then a meat, such as steak or turkey, several vegetables, including both green and starchy, and dessert, such as apple pie or ice cream and 1 ounce (28.35 Gm.) of candy. From a study of these experiments sleep

baths (temperature of the water, 60 F.) to the same subject on different nights. Twenty-four children were used in the observations. The child remained in each type of bath the same length of time, and the baths were completed five minutes before being put to bed, the lights were extinguished at the usual hour, 8 30 p. m. From the data obtained it can be seen that in some children activity was greater than normal after either type of bath. In some children warm baths seemed to have a quieting effect on sleep while in others cold baths resulted in an equal lessening of activity. The giving of baths to some children seemed to have no effect whatsoever either in increasing or in decreasing sleep movements. A typical example is seen in figure 18. Using the absolute values as established, it can be concluded that baths irrespective of the temperature, have no constant effect either in the production of or in the interference with, sleep in normal children.

Fig. 17—Effect of a heavy meal on the sleep pattern. The continuous curve is for normal sleep; the broken curve for sleep after a heavy meal.

Fig. 18—Effect of a warm bath and a cold bath on the sleep pattern. The continuous curve is for normal sleep; the broken curve for sleep affected by a warm bath; the dotted curve for sleep affected by a cold bath.

Fig. 19—Comparison between cold and warm weather normals. The continuous curve is for cold weather; the broken curve for warm weather.

motility was found to be definitely increased in twenty-three of the twenty-four children. A typical example is shown in figure 17. From the absolute values as shown on the graphs it was seen that in only one child was the sleep pattern unchanged. And while it cannot be said that all cases showed an increase in sleep movements greater than the probable error, yet a very high percentage of the children showed a much greater increase in movement than was seen after any of the experiments with a beverage. This increase in restlessness was especially noticeable in the first hour after retiring, for in only one instance did sleep motility in the first hour approach normal. Activity was much less marked in the second hour than in the first, but in eleven of the twenty-four children motility was still above normal. In many curves the increased activity continued throughout the night. It is concluded from these records that the ingestion of a very large evening meal may be a disturbing factor in normal children's sleep.

THE EFFECT OF BATHS ON CHILD SLEEP

Another procedure often used to induce sleep is the administration of warm baths on retiring, and an experiment was done to determine to what extent sleep motility might be influenced by giving not only warm baths (temperature of the water, 102 F.) but also cold

THE EFFECT OF WEATHER TEMPERATURE ON A CHILD'S SLEEP

An interesting series of experiments was done in order to determine the possible effect of the temperature of the weather on children's sleep. The normal sleep curve that heretofore has been quoted in the experiments mentioned was made during a period of cool or cold weather. This normal might be referred to as winter normal, since the minimum temperature during the period observed was 28 F., and the maximum temperature was 44 F. A warm weather normal was determined using twenty-four children over a like number of nights as the winter normal. During this period the temperature fluctuated from a minimum of 60 F. to a maximum of 84 F. The average temperature during the period, both day and night, was well above 70 F. Of the twenty-four children observed, only one child slept quieter during the hot weather. Fourteen had increased restlessness, and in nine children there was no effect. Considering these figures from a standpoint of probable error, it was found that 42 per cent of the children were less active, 58.3 per cent were more active, and in 37.5 per cent there was no appreciable effect on sleep. A typical example is seen in figure 19.

Attention is drawn to the fact that a normal child has a definite sleep pattern. His activity, once established, will practically always follow the same pattern. It is only when his sleep is disturbed by disease or when he is put under such experimental conditions as to affect his sleep that this pattern changes. Even under experimental conditions, the sleep pattern follows the same general outline, increasing or decreasing in activity as the case may be.

CONCLUSIONS

It is believed that the following conclusions may be drawn from these facts:

1 A child has a definite sleep pattern. This pattern is rarely disturbed except through sickness or certain experimental conditions.

2 The drinking of 6 ounces of warm milk at bedtime seems to produce quiet sleep in normal children. Of the other beverages tested, none seems to affect sleep consistently, one way or the other. The drinking of a beverage containing $\frac{3}{8}$ grain of caffeine produces no more restlessness than was seen after the drinking of an equal amount of orange juice.

3 The taking of a large amount of food at the evening meal, even though the food might be considered plain food, resulted in marked restlessness. In many cases the restlessness continued throughout the night.

4 The giving of baths either warm or cold, on retiring seems to have no constant effect either in the production of, or in the interference with, sleep in normal children.

5 A child sleeps definitely quieter in cold weather than in hot.

478 Peachtree Street N E

ABSTRACT OF DISCUSSION

DR M LIVES ROBERTS, Atlanta, Ga. Why we fall asleep remains an unanswered riddle. The study of sleep, except in its grosser aspects, is so elusive we must be content with the investigation of certain of its physical manifestations and physiologic accompaniments in the hope of ultimately arriving at its essential features. The very multitude of theories which have been advanced speaks for their inadequacy. Most of these are now of historical interest, a few seem sufficiently comprehensive to encompass the known facts of our behavior and physiology during sleep. The essayist has brought to us the study of the measurement of muscular activity during sleep which may be accepted as a measurement of the depth of sleep. His work has been done with great care and precision. His studies of the normal sleep pattern seem sufficiently extensive to establish definitely certain general principles. Although motor activity during sleep cannot possibly give the whole picture of this intricate problem it is probably the most accurate method available at present for the investigation of the depth of sleep and the effect of physical agents on the sleep pattern. If his conclusions are correct that the so-called sleep pattern of the individual child is constant and unchangeable except when influenced by physical agents, the thought presents itself that probably such patterns are determined by the nervous make-up of the child—his spasmogenic aptitude. Many questions present themselves. What, for example, is the behavior of the various groups of children during their waking hours? Are the restless sleepers nervous high-strung children by day? What relation, if any, exists between the child's sleep pattern and his body build? Does the thin wiry child fall in the restless group while the average or overweight child belongs to the quiet group? What influence does heredity play? Does the high-strung nervous parent beget a restless sleeper? The essayist has given us much interesting data, some of it rather upsetting our preconceived notions concerning the effect of certain physical agents on sleep.

DR C LLYSEN MOORE, Portland, Ore. I should like to know whether a careful study has been made of the effects of

ovaltine on children. Cases of what we call "ovaltine nervousness" are reasonably frequent in our practice. This may, of course, be an allergic reaction to one of the elements in ovaltine. We occasionally find children who are allergic to chocolate in any form. Ovaltine for some reason appears to be a most common offender. Have others had a similar experience?

DR CHARLES GLENVILLE GIDDINGS, Atlanta, Ga. I cannot answer Dr Moore's question. I have never studied the matter and do not have any information about it.

HYPOCALCEMIA

ITS RELATIONSHIP TO MIGRAINE

G F NORMAN, M D

EUREKA, CALIF

Cases of idiopathic migraine are becoming fewer and fewer as various etiologic factors are being determined. The relation to allergy in a number of these unfortunate persons is well known and has been recently emphasized by Rowe.¹ The infectious factor, particularly as related to foci around the distribution of the fifth cranial nerve, also is well recognized. However, there exists an apparently unclassified group, and it is with this group that the present paper is concerned.

Observations over the past two and one-half years on patients with this complex, usually classified as migraine with respect to blood calcium determinations, have led to some interesting conclusions. It was first noted that a few of these patients exhibited degrees of tetany varying from very mild, almost imperceptible clinically, to very severe. Hyperventilation in a few very mild cases induced tingling of the extremities and occasionally a positive facial phenomenon. These conditions were quite constantly associated with low determinations of calcium in the blood. It is not assumed, however, that all cases of migraine exhibit these phenomena. As a matter of fact, cases of frank operative tetany that have been observed do not exhibit the characteristic migraine symptomatology.

Numerous cases are apparently associated with disease of the biliary tract. However, the failures of surgery on this system to relieve the unilateral headache are only too well known. The question is raised whether or not the biliary disturbance depresses the calcium regulating mechanism or, on the other hand, that the calcium disturbance per se favors pathologic changes in the biliary system. No attempt has been made in the present study to clarify this point.

For this complex I propose the term "migraine-tetanic syndrome" conforming to the idea that a degree of hypoparathyroidism exists and that the latter condition exists more frequently than is generally accepted.

The methods employed to estimate calcium in the blood were first the method of Tisdall² and more recently that of Roe and Kahn³ because of its simplicity.

Normals for each were established ranging from 10.5 to 11.5 mg for 100 cc of blood. This is practically confirmed by the recent work of Inskeep⁴ who employed calcium lactate in raising the calcium level.

Spinal fluid calcium representing the diffused fraction in the body has been estimated in a number of the

patients under observation in this series and found to parallel rather closely the total serum calcium. There has been no instance of nephritis or nephrosis with the possible exception of case 4, in which an albuminuria developed that disappeared with rest. The chemical reactions of the blood and spinal fluid, however, seem quite relevant, a low total serum calcium being accompanied by a correspondingly low determination in the spinal fluid, e. g., from 3.4 mg to 5 mg.

The close relationship of migraine to epilepsy⁵ has frequently been stressed in the past, and recently⁶ acidosis treatment has been instituted for the latter condition. Tetany is also an accompaniment of alkalosis together with low calcium ion values. Conversely acidosis increases the calcium ion concentration in the circulating blood. Observations have been made that epileptic attacks may be mitigated by the exhibition of calcium. This I have in a minor degree been able to confirm.⁷ On the basis of vascular contraction occasionally observed on the affected side in migraine, may one not assume the relaxing effect on the calcium ion?

Sterling⁸ observed a case in a boy of 9 years and makes the assertion that it is a question of cases of migraine complicated at times by a latent tetany, at times by crises of manifest tetany evolving at the height of attacks of migraine or quite independent of them. This, however, is not the impression gained by the present study, since it is felt that the two conditions are definite components of a definite syndrome.

Without entering into a discussion as to the mechanism of parathyroid function in relation to vitamin D, I assume that the latter may quite well substitute for the former in raising plasma calcium.^{2a} In this work both parathyroid extract and viosterol have been employed, but in most cases the latter because of its ease of administration. As previously observed, it is interesting to note that cases of operative tetany seen clinically do not exhibit the migraine syndrome. Consequently, the conclusion seems inevitable that in certain individuals a migrainous or convulsive tendency is held in check by the parathyroid glands by virtue of their power to maintain the proper level of serum calcium or by their apparently complementary factor, vitamin D.

In accordance with the work of Dragstedt,⁹ who observed that tetany could be induced by the ingestion of animal protein in parathyroidectomized dogs and inhibited by a diet of milk and bread, it was observed that an attack could be induced in a patient under treatment with viosterol by a diet high in protein value.

Objection has been raised recently to these studies¹⁰ in that mainly total calcium studies were employed and the diffusible fraction was not estimated. Parathyroid extract is known to increase both the diffusible and the nondiffusible fraction. It is admitted that in a given experiment "the total increase in the serum calcium after the ingestion of a calcium salt is due to an increase

in the diffusible calcium fraction alone, while the nondiffusible calcium remains unaltered throughout the experiment."¹¹ It will be observed in the cases cited and all those studied with the administration of viosterol that there was an increase in the total serum calcium. This increase has been assumed in the present study to occur in the diffusible fraction, since it has also been shown that this fraction is raised by ultraviolet irradiation of the body.¹² The same authors contend¹³ that tetany due to the alkaline shift in acid-base balance, viz., alkalosis shows no decrease in diffusible calcium and is probably not associated with a lowered ionization of calcium. The assumption is made that the diffusible and the ionized calcium are identical. According to Cantarow,¹⁴ this is by no means the case and as yet there is no entirely satisfactory method by which the concentration of calcium ionization may be determined, it probably depending on hydrogen, bicarbonate and phosphate ion concentration. Of the diffusible fraction, from 4.5 to 5.5 mg, according to various investigators, less than one half, namely, about 2 mg, exists in the ionized state.

The mechanism of action of parathyroid hormone and of vitamin D is naturally still speculative. It has been observed that vitamin D increases both the calcium and the phosphorus content of the blood in contradistinction to the former parathyroid, which causes, in conjunction with an increase in calcium, a primary drop in the phosphate value.

About seventy patients complaining of periodic headaches associated with nausea and vomiting have been studied and most of them have been improved by the oral administration of viosterol or the parenteral administration of potent parathyroid extracts. Naturally, many cases have been studied in which normal calcium values obtained and are not included here.

The following abbreviated typical case histories are cited.

CASE 1—J. J. N. a man aged 51, a meat cutter April 4, 1930, complained of recurring headaches, over a period of years, associated with vomiting. The attacks at this time were coming about every week. They lasted about one day. He was completely disabled from work at the time. Physical examination revealed no abnormalities except a slight tingling of the hands on hyperpnea. The urine and hemoglobin were normal, the blood Wassermann reaction was negative. The patient was given viosterol, three drops three times a day, with complete relief. He reported two years later that no more attacks occurred as long as he took the drops.

CASE 2—H. M. Z. a man aged 42, a farmer, April 15, 1929, complained that as long as he could remember he had had recurring headaches in the region of the right eye, associated with nausea and vomiting. The pain was occasionally generalized all over the head. There was marked photophobia during the attacks, with paresthesia of the hands and forearms but no cramping of the muscles. The family history revealed the same symptom complex in the mother. Physical examination revealed infected teeth which were removed. Roentgenologically the gallbladder was found to fill poorly and to empty slowly. There was no relief from the removal of foci of infection, and from the institution of a carefully studied diet with a view to the elimination of offending proteins. The blood calcium was 7.5 mg. The patient was given viosterol 4 drops three times a day. He reported a few months later that his headaches were absent as long as he took the medicine but reappeared when he discontinued it. The blood calcium

7 Calcium studies are available in one case of operative parathyroid tetany which finally terminated in death because of poor cooperation on the part of the patient. There was no heredity suggesting epilepsy, but the condition gradually progressed in severity. At first only slight spasms were present. These became associated with unconsciousness at a late date, the patient finally succumbing in typical status epilepticus. The serum calcium here normally read around 5 mg per hundred cubic centimeters.

was again determined while viosterol was being taken and found to be 95 mg

CASE 3—Mrs J A H aged 28, a housewife, March 5, 1932, complained of headaches of increasing severity, always localized around the right temple and eye, associated with nausea and vomiting and of definite periodicity. At times the feet would become cramped severely. There was no family history of migraine. Physical examination revealed essentially nothing abnormal. There were no discoverable foci of infection and the usual laboratory tests were negative. There was apparently no eyestrain and I was assured that her glasses were properly fitted. Elimination diets were likewise instituted without effect. The blood calcium during an attack read 65 mg. Ten units of parathyroid extract was administered as soon as the determination was made, supplemented by 10 drops of viosterol three times a day. There were no headaches until two months later. At this time the patient had also become pregnant and had partaken of a heavy meal of venison. Bread, milk and fruit juices were reinstituted and the attack passed off readily, the patient reported that the headaches "were not nearly what they used to be." Shortly thereafter the blood calcium read 12 mg. Two months later, in which interval she had contracted influenza and had experienced high fever with pain in the head, she reported that this pain was entirely different from the old sick headache. The blood calcium rose to 15.99 mg, at which time viosterol was discontinued. She was subsequently delivered of a normal child and without further administration of viosterol remained perfectly well until July, 1933. A sick headache developed at this time and the same medication was reinstituted, again with relief.

Blood and Spinal Fluid Readings in Case 4

Date	Medication	Total Serum Calcium	Spinal Fluid Calcium	Symptomatology
11/15/33	None for four days	7.5	3.5	Headache nausea vomiting and mild carpopedal spasm
11/21/33	Viosterol 10 drops t i d	10.0		No headache or nausea slight muscle hyper irritability
11/25/33	Viosterol 10 drops t i d	9.11	4.64	Perfectly well blood pressure cuff readily induced paresthesia of arm

September 26 after the drug had been discontinued for fifteen days, a typical attack of migraine developed. The blood calcium was 8.6 mg and the spinal fluid calcium was 4.2 mg. Resumption of the usual medication in 5 drop doses has prevented further spells, but the patient reported recently a dull pain in the occipital region on stooping but none of the old disabling attacks. November 22 the blood calcium was 9.6 mg.

CASE 4—Mrs S A, aged 26 a nurse, Aug 13, 1932 referred by Dr J F W for thyroidectomy, complained of severe attacks of headache, nausea and vertigo which were worse with the menses, becoming more frequent and more severe, there was extreme nervousness tingling of the extremities and cramping of the calf muscles. Satisfactory determination of the basal metabolism could not be obtained, owing to extreme nervousness. The condition had existed since she was 10 years of age. The appendix and the gallbladder had been removed elsewhere in an effort to overcome the headaches. There was no history of food idiosyncrasy and no demonstrable foci of infection existed. Physical examination revealed a fine tremor of the hands and a small enlargement of the thyroid. The pulse was 120 and the blood pressure 220 systolic 130 diastolic. The Chvostek sign was slightly positive as was also Trousseau's. Hyperpnea induced marked tingling of the extremities. A diagnosis of hyperthyroidism and hypoparathyroidism was made and a partial thyroidectomy performed without serious reaction. The patient's nervous condition was improved, the blood pressure receded to 164 systolic 120 diastolic and the pulse to 76. However the headaches and vomiting continued unabated and were of such severity as to require large doses of morphine to control them. The blood calcium was found to be 7.6 mg. This was taken during a particularly severe paroxysm of pain which was the first real attack that I observed. At this time

the patient complained of numbness everywhere and exhibited carpopedal spasm. Parathyroid extract, 20 units, was immediately administered, with dramatic relief. This was supplemented with 10 drops of viosterol three times a day. She was able to return to work in two days and reported complete cessation of the head pain and nausea. After about one month the dosage of viosterol was reduced to 7 drops, which promptly resulted in a mitigated attack. Ten drops was immediately resumed and, in addition, parathyroid extract 10 units every other day for eighteen doses. This again resulted in complete relief. The latter medication was administered elsewhere and no chemical determinations were available. An attack of albuminuria with hypertension compelled her to resort to bed rest and a restricted diet. Nov 15, 1933 after interruption of viosterol for four days, the headaches and nausea associated with mild carpopedal spasm recurred. The blood pressure readings had receded to 156 systolic, 90 diastolic, and examination of the urine revealed no pathologic changes.

The blood and spinal fluid readings in the accompanying table seem very significant, revealing a symptomless case with the chemistry of calcium approaching normal.

CASE 5—R K, a schoolboy, aged 12 years, May 16, 1932, complained of irregular respiration on falling asleep cramping of the hands and feet, and a severe boring pain in the region of one eye or the other associated with nausea and vomiting, all coming in definite attacks. A severe attack of scarlet fever six months prior to the present illness was followed by tonsillectomy. Headache was particularly noted when the patient awakened suddenly from a spell of apnea. Apnea was always followed by a period of hyperpnea. Physical examination revealed blurred disk margins in each fundus with some exudate on the vessels. Tingling in the extremities was readily induced by hyperpnea. The Chvostek sign was then positive. No other abnormalities were noted. Spinal puncture revealed clear fluid under normal pressure, the cell count showed 37 mononuclears and globulin strongly positive. The blood and spinal fluid Wassermann tests were negative. The blood calcium was 6.5 mg. Examination of the urine was negative. There was an immediate improvement when viosterol was administered. The attacks of irregular respiration ceased and there were no further headaches. One month later the blood calcium was 13.33 mg. Medication was discontinued without consent and the symptoms all recurred. A dosage of 15 drops was commenced again with relief. Calcium then read 12.5 mg. Despite medication after a period of complete freedom, the patient experienced a very severe spell and died in convulsions following a period of apnea.

The impression gained from this case was that the condition was chronic encephalitis complicated by a latent hypofunction of the parathyroids or that the type of respiration induced reduced the ionized calcium to the point of hyperirritability.

CASE 6—Mrs P E J, a housewife aged 63, complained, Oct 13, 1931, of attacks at night characterized by convulsions, cyanosis and loss of consciousness followed by deep sleep, all associated with severe one-sided headache but no nausea. The onset had been recent. She also complained of some cramping of the calf muscles and drawing in of the thumbs. Physical examination revealed some cardiac enlargement with a blowing systolic murmur. The blood pressure was 166 systolic, 110 diastolic. The usual laboratory tests all gave normal results and the blood calcium was 8.8 mg. Viosterol 3 drops three times a day, was administered and two months later the patient had experienced only one attack and felt much improved, with the calcium reading 9.6 mg. The dosage was then increased to 5 drops and in November, 1932, the patient reported that there had been only one additional spell, and that this was definitely followed by a right-sided headache but no nausea. Again she discontinued medication completely on her own initiative and in two weeks the symptoms recurred, again to be held in check only by resumption of medication. July 20, 1933, the blood calcium was 9.7 mg. September 20, after interruption of the drug for one week the blood calcium was 10.2 and the spinal fluid calcium 4.2. October 22, the patient reported one attack.

followed by a very severe right-sided headache despite the 5 drops of iosterol. The thumbs cramped vigorously and this was particularly noticeable previous to the spell. The blood calcium was 7.9 mg. Apparently in this case a larger dose was required, and this has been instituted.

SUMMARY

A number of cases of typical so-called idiopathic migraine have been studied with respect to blood calcium values, which have been found to be uniformly somewhat depressed. Six cases have been chosen at random, ranging from relatively mild to very severe, the last being associated with epileptiform convulsions. This entire group has been benefited by means taken to raise the values of calcium to normal.

CONCLUSIONS

1 It is assumed that symptoms of migraine and tetany are maintained dormant in this group by the calcium regulating mechanism.

2 One or the other complex may predominate. Whether unilateral headache and nausea with or without vomiting should be included in the picture recognized as tetany remains for further study.

Clinical Notes, Suggestions and New Instruments

THE USE OF SALYRGAN IN ONE PATIENT OVER A PERIOD OF THREE YEARS FOR RECURRING ASCITES AND EDEMA ASSOCIATED WITH CARDIAC FAILURE

CARTER SMITH, M.D., ATLANTA, GA.

From the Cardiac Clinic of Emory University School of Medicine

Mercurials have been used as diuretics for many years. More recently salyrgan, an aqueous solution containing about 37 mg. (one-half grain) of metallic mercury to the cubic centimeter, has been used in treating patients with abnormal collections of fluid in the tissue or body cavities.

That mercury may be a renal irritant is a well known fact. Salyrgan, however, has been used repeatedly over long periods of time even in those with previously existing renal disease without untoward effects.¹ Occasionally patients are encountered who have an idiosyncrasy to mercury and reactions such as convulsions or anuria may occur. Only one such instance has been recorded in the literature,² and this patient made an uneventful recovery. Because of this very infrequent idiosyncrasy caution must be used in administering the initial dosage of this drug. It should be given first in 0.5 cc. doses intramuscularly. If no reaction occurs within forty-eight hours it may then be given in doses of from 1 to 4 cc. intravenously or intramuscularly.

The present case report is added to the literature to show that salyrgan may be used at frequent intervals over a long period of time without causing renal damage and that it may be quite efficacious in the removal of ascites and edema and thereby increase circulatory efficiency.

M. W., a native Negress, aged 19 years, was admitted to the Grady Hospital in May 1929. The diagnosis was rheumatic heart disease with mitral stenosis and an acute circulatory failure. She stated that she had experienced attacks of rheumatism all her life. The last attack of acute polyarthritis occurred six months before. Symptoms of cardiac failure first began three months before.

She was rather small and very dark and was in an advanced state of cardiac decompensation. There was moderate dyspnea and cyanosis. There was very little orthopnea. The peripheral

veins were distended. There was a moderate pitting edema of the lower extremities. The liver was about 6 cm. below the costal border, tender and pulsating. The abdomen was tense with ascites. The heart was considerably enlarged. A teleroentgenogram showed the supracardiac width to be 4 cm., the right margin 6 cm. and the left margin 12.5 cm. The total diameter of the chest was 28 cm. There was a systolic vibration at the apex. No definite thrills were detected. The apical first sound and the pulmonary second sound were accentuated. There was a harsh (grade 4) systolic murmur over the entire precordium but was best heard at the apex. In the left lateral position a mid diastolic murmur was heard at the apex. The heart rate was 120 per minute and the rhythm was regular. The blood pressure was 115 mm. systolic and 70 mm. diastolic. There was no evidence of arteriosclerosis.

There was 2 plus albumin in the urine and there were a few red blood cells and casts in the sediment. The phenolsulphonphthalein excretion was 60 per cent in two hours. The blood constituents were normal. The blood Wassermann was negative and the blood count was not abnormal.

The abdomen was tapped and 5 liters of straw-colored fluid with a cell count of 170 lymphocytes per cubic centimeter was withdrawn.

There was an irregular elevation of temperature, and blood cultures made on three successive days showed a growth of nonhemolytic streptococci. Positive blood cultures were never obtained again.

The patient remained in the hospital five weeks, the abdomen was tapped at weekly intervals, she was digitalized, and circulatory competence was finally established. During the next fourteen months there were thirteen admissions to the hospital for recurring cardiac failure and an abdominal paracentesis was necessary every seven to fourteen days, from 3,000 to 5,000 cc. of fluid being withdrawn each time. One year after her first admission to the hospital she developed another attack of acute polyarthritis. There was an irregular elevation of temperature for about five weeks and subcutaneous painful nodules occurred over the long bones. These appeared and disappeared within a period of forty-eight hours. Cardiac failure became marked even with complete rest in bed.

Treatment thus far had consisted of rest in bed, digitalis, sedatives, diuretics by mouth, and salyrgan at infrequent intervals. Abdominal paracentesis was necessary almost every week during the first year of her illness.

During the second year of the patient's illness the regular administration of salyrgan intramuscularly was begun in doses of 1 to 2 cc. at intervals of three to seven days. Diuresis was always prompt and profuse, about 5 liters of urine was excreted during the first eighteen hours after an injection. Preceding the injections with ammonium chloride in 1 Gm. doses did not increase the diuresis. After the regular administration of salyrgan was begun paracentesis of the abdomen was no longer necessary. Circulatory competence was greatly improved. During the second year of her illness the hospital admissions were reduced from thirteen to two and during the third and fourth years there was only one entry into the hospital. During the past three years she has been given 175 cc. of salyrgan. No abdominal paracenteses have been done during this time and her circulatory competence has been such as to allow the performance of light household duties.

A study of the patient's renal function after the prolonged administration of salyrgan shows no evidence of renal damage. There is now only a trace of albumin in the urine, no red cells are seen and only an occasional cast. The blood chemistry is within normal limits and the phenolsulphonphthalein excretion is 50 per cent in two hours.

Salyrgan has proved of inestimable value in removing ascites and edema and improving circulatory efficiency in this patient and no evidence of renal damage can be demonstrated after its continuous use for three years. We believe that it should be used more often for the removal of abnormal accumulations of fluid in the body tissues or cavities and that it may be used without fear of renal damage even in those with preexisting renal disease.

A SKIN MANIFESTATION FROM THE EXCESSIVE
ADMINISTRATION OF VITAMINS

F F PFISTER MD WEBSTER S D

Skin eruptions of the eczematous type are not unusual in early childhood. Rashes at all akin to true eczema are classified as eczema, and the usual routine of local applications is followed with various manipulations of diet, it being accepted as a fact that the condition is an eczema without a doubt. I do not say that eczema is caused by excessive doses of vitamins but that certain cases which are classified with eczema are readily cleared up by the discontinuance of the vitamin with no local applications whatever.

The type of rash to which I refer may be described as a fine papular rash superimposed on an erythematous base, looking much like many of the early eczemas. I have not seen any that presented a weeping surface. The face has been the most common site for the eruption.

The causative factor may be a particular idiosyncrasy to vitamin solutions, but I believe it is due to an excess of vitamins. It has been noted chiefly since the use of concentrated vitamin solutions such as viosterol and halibut liver oil. I do not believe the excessive ingestion of fat need be considered, as the cases to which I refer had been treated with vitamin concentrate.

I think the impression prevails among medical men that vitamins can be given in any amount, almost with impunity. But I believe that as more and more is known about vitamins it will become obvious that they too have their limitations. Until a definite measuring stick is found to outline the limits of vitamin dosages, this possible source of some of the difficulties must be kept in mind.

I shall report here only two cases which to me are striking examples of a skin manifestation from the excessive administration of vitamin. I am exceedingly familiar with the first case to which I refer, as it occurred in my own family.

CASE 1—F P, a boy, aged 11 months, had progressed nicely and enjoyed normal growth and development. In addition to his diet he had been given cod liver oil, 3 teaspoonfuls a day. His skin was perfectly clear and there had been no eruptions. When the patient was 11 months old, halibut liver oil with viosterol was started in place of cod liver oil. I noticed on the fourth day after the oil was started that there was an eczematous eruption, very fiery red and with a papular rash showing through the reddened area. At this time I questioned about the various articles of diet there had been no deviation, no change in soap or anything unusual except that haliver oil with viosterol had been given instead of cod liver oil. Further inquiry revealed that through a mistake the baby had received 3 teaspoonfuls of haliver oil with viosterol daily for the four days instead of a few drops as ordered. If I had been purchasing the haliver oil I would have noticed the error before the baby had had sufficient vitamin solution to blossom out in such a rosy eruption. The baby's uncle, a salesman of this preparation had supplied him with a liberal quantity of samples. The oil was stopped and without any treatment the rash cleared up entirely in a few days. He was not given any haliver oil or other vitamin solution for a couple of weeks, until my curiosity caused some experimentation. I again gave the baby 3 teaspoonfuls daily of haliver oil with viosterol and on the third evening the redness recurred and on the fourth day a full-blown eczematoid facial eruption appeared. It cleared again by the mere stopping of the oil. He was again put on haliver oil with viosterol, 15 drops a day and the skin showed no eruption whatever. However, about five months later with a clear skin in the interim he got hold of some gelatin capsules containing 3 minims (0.2 cc) each of haliver oil with viosterol, and as near as I could check up he had eaten twenty-seven capsules at one time. The next evening he again presented the eczematoid rash which cleared in a few days after removal of haliver oil from the daily regimen. Since I have exercised more caution in the amount of haliver oil given him he has had no eczematoid eruptions whatever. Nothing was noted in regard to the rest

of the body—no gastro-intestinal upset and no abnormal manifestations of any kind were noticed.

CASE 2—P S, a boy, aged 10 months the son of a minister, was brought to me with a skin eruption on the face, of two weeks' duration. It appeared to be much like an eczema—a papular rash over a reddened area. The baby's uncle, a druggist, had given calamine lotion and white tar ointment with absolutely no relief or clearing of the rash. Since I had been on the watch for these certain types of eczematous rashes, the first question I asked was the kind of vitamin solution given the baby. The mother answered that she had given the child cod liver oil until just a few days previously, when she had started the baby on viosterol giving 3 teaspoonfuls daily. The parents had also been the recipients of two large size bottles of viosterol, which had been given them and not purchased, and consequently there was a delay in noticing the error in dosage. The baby was taken off viosterol no local applications were given and within four days the skin was entirely clear.

These two cases, of course are the extreme both in dosage and in the severity of the rash. My experience with skin conditions associated with vitamin overdosage has prompted me to be on the lookout for this manifestation, and I have encountered many facial rashes of varying degrees of severity which have cleared up after the vitamin solution was discontinued and the dosage was later adjusted. I have reported these observations at a medical society and I have several letters from physicians in the nearby towns who had noted several cases that cleared up after the vitamin solution had been stopped or the dosage adjusted.

No attempt has been made to go into the theoretical causative factors concerned in this group of cases. A general belief among both the medical profession and the public is that large doses of vitamin preparations can be given without any deleterious effects. The observations in the cases reported will tend to refute this belief.

THE PROTECTION OF BODY CASTS BY CELLOPHANE

BERNARD N F COHN MD PHILADELPHIA

The adequate handling of children to prevent soiling of body casts presents a difficult problem even in orthopedic institutions where the nursing personnel is especially trained to care for such patients. In general hospitals one depends on a regimen of watchful waiting to cope with such a situation often without success. It taxes the patience of the surgeon who applies a satisfactory body cast only to find it so soiled in a few days that a new one is required. In order to obviate such altogether too frequent occurrences a simple and inexpensive means was sought.

Various methods for accomplishing this purpose are already in vogue the most common of which is shellacking the part around the perineal region or covering it with oiled silk. Neither of these is entirely satisfactory from the standpoint of time and expense involved. It has been found that cellophane affords the easiest and most inexpensive means to protect a cast.

After a cast has been trimmed and has set sheets of cellophane are cut to conform with the configuration of the perineal region. The edges are then held in proper position with adhesive tape. It is best to use sufficient cellophane to extend at least ten inches above the opening for the genitalia and for the same distance along the medial surface of the thighs especially in young children. This procedure can be executed easily by any nurse even without special training in the care of children in body casts.

The cellophane should be changed at least every other day, since exposure to moisture for longer periods renders it moldy and foul smelling.

It is not necessary to purchase sheets of new cellophane for this procedure. Today many articles are wrapped in cellophane and the wrappers may be stored in a dry place until needed. Cellophane covers from loaves of bread, for example serve adequately.

Special Article

INTRAVENOUS HYDROCHLORIC ACID IN THE TREATMENT OF DISEASE

More than thirty years has passed since Metchnikoff¹ proposed his now famous thesis of phagocytic immunity. The stimulus furnished by his work was of inestimable value to the subsequent rapid development of immunology, but the original views held by Metchnikoff and some of his followers have been modified in the light of more recent investigations. It is now generally appreciated that certain humoral factors are necessary even for the phagocytic reaction. As stated by Topley and Wilson,² "The views of the extreme 'cellular' school are obsolete in their original dogmatic form." Despite present teachings as to the complex nature of immune reactions, the principle of phagocytosis in the original restricted sense has enjoyed periodic recrudescence in its practical applications to therapeutics.

About five years ago, stimulated by the results of Hanes³ in the treatment of pruritus ani by the local injection of hydrochloric acid, Burr Ferguson⁴ of Montgomery, Ala., proposed the parenteral use of this therapeutic agent in other diseases. Ferguson⁵ wrote

For several years I had been searching for a better agent than various preparations of mercury, arsenic, quinin or vaccines, for the control of the white cells, the administration of which agents was frequently attended with much pain or a pronounced inflammatory reaction. In November, 1927, I had the good fortune to find this better agent for the stimulation of the phagocytes in hearing a discussion of pruritus ani and its treatment by the local injection of a 1:3000 solution of hydrochloric acid, by Dr. Granville S. Hanes of Louisville. Seven years before, the speaker said he had determined that pruritus was an infection and that he would attempt the elimination of the infecting organisms by the injection of this acid solution under the site of the foci of pruritus. Plates were shown of many cases of pruritus and prolapse of the rectum, before and after this therapeutic procedure, which left one in no doubt of its efficacy. Apparently the germs had been burnt up by their immersion in the acid solution and the manifestation of their presence were healed. Dr. Hanes, however, said that this purely local effect in no way explained the improvement he had seen in some of these patients who had eczema or wounds in other parts of the body, in which the clinical results were quite as good as at the site of the injection of the acid, and that he was utterly unable to explain these phenomena.

This talk of Dr. Hanes furnished the clearest confirmation of the truth of the generalization of Metchnikoff that "the one constant element of immunity, whether innate or acquired, is phagocytosis" that I had yet heard, and I knew that the agent for which I had searched had been found. For it was reported that there had been few reactions after the injection of very large quantities of this solution, and I further knew that such clinical results could only be seen with the accompanying marked stimulation of the white cells. Further it was fascinating to think of putting this normal reagent of the stomach into the body by its injection.

Determinations done in the City Venereal Clinic with a variety of infections the next day proved that the subcutaneous injection of the acid solution was immediately followed by an increase in the numbers of the white cells. During the

following days the expected clinical results were seen in a wide variety of infections. Any therapeutic procedure, however, is always attended with objections. With this procedure these complaints came from the patients, many of whom did not like the swelling or bumps that were left for several days after the subcutaneous injection of the acid. To overcome this untoward effect, the acid was injected intramuscularly. This procedure was too uncomfortable and could not be done more than about twice a week, and frequently a patient would be seen who really needed a more frequent stimulation of the phagocytes.

About two years ago, letters were exchanged frequently by the writer and Dr. Francis E. Park of Boston on the use of the hydrochloric acid in infections. In one of Dr. Park's letters he asked why the acid solution might not be injected intravenously. I could see no reason why it might not be done safely. So I took two Negro patients from the clinic, my assistant and myself, for the determinations, following the injection of 10 cc of hydrochloric acid in distilled water 1:1,500 with much benefit to the patients and no harm or inflammatory reaction to the controls. However, the following leukocytosis was not as well maintained as that after the intramuscular injection. This objection was trivial, however, as the cells could be much oftener stimulated. I am delighted to take this opportunity to thank Dr. Park for his question.

To use the hydrochloric acid intravenously one must overcome a number of inhibitions, first that acid cannot be put directly into the alkaline blood, for fear of the dreaded acidosis, secondly that one must use a specific poison or anti-toxin, for its particular effect against the infecting organisms, and, last that some allergic reaction may follow the injection of an acid.

The report in the foregoing pages shows that there is no danger in the injection of this acid into the blood stream. Further, that this intravenous injection of this drug that has been used since the time of Glaber as an aid to digestion, is altogether comparable to the intravenous use of mercury and arsenic in this generation. These drugs had been used for several hundred years by the mouth, or by injection, but one rarely hears of them in any way now. The promptness of the clinical results caused this change. The bismuthide, calomel and other mercurial preparations and the various preparations of arsenic did stimulate the white cells, but mercurochrome, metaphen and other intravenous injections with this same active principle were much more potent creators of hyperleukocytosis.

Following Ferguson's glowing reports⁶ of clinical recovery in practically every disease in which the new remedy was tried, enthusiastic support came from other physicians, several of whom apparently believe that they have found in this simple solution a long sought for panacea.

It would be surprising indeed if intravenous therapy of this sort, so assiduously and earnestly supported and promoted by reputable clinicians and by at least one manufacturer of solutions for intravenous use, should not long ago have been subjected to careful scrutiny by its proponents from the standpoints both of pharmacology and of immunology. Yet it appears that this new treatment was tried on human beings on a purely empirical basis and without known experimental background of any kind.

The idea of stimulating phagocytosis in the prevention and treatment of disease is not new. This problem

has been the subject of extensive investigation by a host of workers for many years

Mikulicz,⁸ for instance, thirty years ago, tried with indifferent success the effect of a number of substances on mobilization of leukocytes in peritoneal exudate in an attempt to protect the peritoneum against infection, a project more recently brought to successful consummation by Steinberg and Goldblatt.⁹

Gehrig¹⁰ in 1915 presented a detailed and comprehensive list of substances used by various observers including himself, which comprises a large portion of the active agents known to pharmacology and immunology. Curiously enough hydrochloric acid is listed among the agents found to be inactive in this respect.¹¹ True, reference to the original paper, published forty-five years ago, reveals that the acid was given by mouth and not parenterally, yet if Ferguson's thesis as to the mode of action of this agent on the acid-base equilibrium is correct, the acid should be quite as active orally as by any other route, as will be brought out later. While some of the substances used for this purpose do undoubtedly produce a mobilization of white cells in the blood stream, the work of Wright and Douglas¹² and of others has demonstrated that phagocytosis can occur only in the presence of the proper humoral factors ("opsonins").

Leukocytosis *per se* therefore does not necessarily mean increased resistance to disease. Wells¹³ has said "Many substances have been used to increase the number of leukocytes in the circulating blood in the hope of increasing resistance to infections, a result that does not seem to follow artificial leukocytosis with any recognizable uniformity."

To establish claims of therapeutic benefit through the agency of leukocytosis, it is necessary to demonstrate that mobilization of white cells actually occurs (and in the light of recent work, this is far more difficult than is commonly supposed),¹⁴ that extensive phagocytosis of the organism in question may take place,¹² that recovery occurs in treated animals or patients in substantially greater proportion than in parallel controls. This of course would not prove in any case that the leukocytes were entirely responsible for recovery but would merely indicate that there is a reasonable probability that they have aided in the improvement.

In evaluating the results claimed by Ferguson and his adherents, a number of pertinent questions must be answered:

1 What is the precise nature of the therapeutic agent, what is meant by "1 1,000" or "1 1,500" hydrochloric acid?

2 Does this solution actually produce leukocytosis? If so, by what mechanism?

3 If a leukocytosis is produced, is phagocytosis materially increased?

4 What, if any, dangers are involved in the intravenous injection of hydrochloric acid?

5 Do such injections have effects of possible therapeutic value other than the alleged stimulation of phagocytosis?

6 Is the clinical use based on adequate experimental evidence?

7 Is there satisfactorily controlled evidence of therapeutic benefit in clinical cases?

THE THERAPEUTIC AGENT

To describe a solution of hydrochloric acid as "1 1,000" is ambiguous. This may mean, for instance 1 part by weight of hydrogen chloride in 1,000 parts by weight or by volume of water, or 1 part by weight or by volume of a solution of concentrated hydrochloric acid (about 35 per cent by weight of hydrogen chloride) diluted to 1,000 parts by weight or by volume with water.

With but a single exception, a brief note by J H Hendren,¹⁵ no mention is made in the literature of the possible ambiguity involved in the statements of acid content. According to Hendren "one drop of C P hydrochloric acid in three ounces of distilled water will make the desired solution [1 1,500]" Apparently "1 1,500" in this case is intended to mean one part by volume of approximately a 35 per cent solution (by weight) of hydrogen chloride, made up to about 1,500 parts by volume with water. If such confusion exists among the proponents of this therapy, those interested in estimating its true status must necessarily meet with great difficulty at the outset.

In order to determine accurately the nature of the solution widely employed, the A M A Chemical Laboratory was asked by THE JOURNAL to examine specimens of ampules purchased on the open market. These were manufactured by the Loeser Laboratory, New York, active commercial proponent of intravenous hydrochloric acid. The A M A Chemical Laboratory reported as follows:

"LOESER'S INTRAVENOUS SOLUTION"

Original specimens of Loeser's Intravenous Solution, Hydrochloric Acid 1-1000 and Hydrochloric Acid, 1-1500 (Loeser Laboratory, New York) were submitted to the A M A Chemical Laboratory for examination at the request of THE JOURNAL.

The labels on the ampules for the respective concentrations bore the following statements:

Hydrochloric Acid
1 in 1000
10 cc Plus

A sterile solution of one part C P Hydrochloric Acid in 1000 parts of distilled water for injection purposes

Loeser Laboratory
New York

Hydrochloric Acid
1 in 1500
10 cc Plus

A sterile solution of one part of C P Hydrochloric Acid in 1500 parts of distilled water for injection purposes

Quantitative determinations yielded the following:

	Ampules labeled			
	1 in 1000	1 in 1500		
Per cent by weight of HCl found	0.0322	0.0216		
Gm of HCl found per liter	0.3209	0.2156		
Gm of HCl found per 1000 Gm of solution	0.3222	0.2164		
Minims of diluted hydrochloric acid U S P per 10 cc (based on upper and lower U S P limits)	0.47-0.52	0.31-0.35		
Per cent by weight of claimed contents for 1 liter of solution	(A) 78	(B) 69.9	(A) 78.6	(B) 70.5
(1 1000 and 1 1500 by volume respectively)				
Per cent by weight of claimed contents for 1000 Gm of solution	(A) 92.1	(B) 83.7	(A) 92.7	(B) 84.3
(1 1000 and 1 1500 by weight respectively)				

NOTE.—(A) This figure is based on a strength of hydrochloric acid of not less than 35 per cent by weight of HCl, as

1 Hendren J F Clin Med & Surg 39 815 (Nov) 1932

8 von Mikulicz J Arch f Klin Chir 73 147 1904

required according to the Report of the Committee on Guaranteed Reagents of the American Chemical Society

(B) This figure is based on a strength of 38.5 per cent HCl, indicated on the label of the product of a reputable manufacturer as the upper limit of HCl content

It will be noted that wide variation (e. g., 92.7 to 70.5) in per cent by weight of claimed contents is evident, depending on what strength of acid was used and whether or not the acid was diluted in proportion by weight or by volume. If the percentage of HCl in the concentrated acid was above 38.5, the percentage by weight of claimed content found present in the ampules would be still less.

It is to be noted that 10 cc of the solution in the 1,000 ampule contains the equivalent of about $\frac{1}{2}$ minim of diluted hydrochloric acid U. S. P., 10 cc of the solution in the 1,500 ampule contains the equivalent of about $\frac{1}{3}$ minim.

Not only, then, is there ambiguity in the statements of concentration in the literature, but the commercial solutions that were examined for *THE JOURNAL* appear not to contain the claimed amount of HCl, no matter on what basis calculated. It is not difficult to estimate the probable therapeutic effects of $\frac{1}{3}$ to $\frac{1}{2}$ minim of diluted hydrochloric acid U. S. P., which the A. M. A. Chemical Laboratory found to be the equivalents of the Loeser solutions.

PRODUCTION OF LEUKOCYTOSIS

It seems not unreasonable to demand that, in order to establish a claim for alteration in the level of the white cell count by a pharmacologic agent, the change must exceed the probable error of the method used for counting and must exceed also the maximum range of the variations that are known to occur in the normal individual from hour to hour during the day. In none of the material presented by Ferguson or by his colleagues is there a description of the method used for estimation of the cells, nor is there anything which indicates an appreciation of the large error inherent even in the most meticulous technic. Many of the alleged leukocytoses obtained by these clinicians fall within the usual error of counting (probably at least 10 per cent), others fall readily within the range of the large natural fluctuations demonstrated by Shaw¹⁴ to occur in normal persons, independent of food intake, exercise, sleep or body temperature. As reported by Piney¹⁶: "during the twenty-four hours, the total leukocytes of man exhibit two tides, each of about twelve hours' duration. The day tide begins in the forenoon, reaches its flood in the afternoon, and ebbs during the evening. The night tide begins in the evening, reaches its height in the hours after midnight, and falls away in the morning." According to Kolmer and Boerner¹⁷: "A count made during the afternoon may be 2,000 higher than one made in the morning." Shaw's work indicates that even a greater normal range is possible. There is no evidence in the literature examined that this important source of error was even considered by the proponents of intravenous hydrochloric acid.

As the reported changes in cell count following the acid injections appear in large part to tend in the upward direction, it seems not improbable although this is by no means definitely proved, that a leukocytosis of small magnitude actually does occur in some cases. But as stated by Jordan,¹⁸ "the production of

leukocytosis is in itself of little value unless at the same time the amount of opsonin in the blood, the specific opsonic index, is high enough to favor phagocytosis."

The published literature reviewed on intravenous hydrochloric acid does not reveal a single determination of the opsonic index.

It has been claimed that the acid mediates its effect through changes in the acid-base equilibrium of the blood. Analogy has been drawn⁵ between the effect of this treatment and the nitrohydrochloric acid treatment of allergic conditions proposed several years ago by Beckman¹⁹. Reference to the latter's work reveals that a dose of 0.6 cc of nitrohydrochloric acid (N. F. V.) was administered orally, properly diluted, four times a day, or a total daily dose of 2.4 cc. This is equivalent in acidity to about 8.9 cc of diluted hydrochloric acid, U. S. P., about 400 times as much acid as was found in 10 cc of Loeser's "1,500" hydrochloric acid, or about 270 times the amount in 10 cc of the "1,000" solution.

Whereas the quantity used by Beckman might conceivably alter the acid-base equilibrium, it is difficult to see how the quantities injected as the Loeser solutions tested by the A. M. A. Chemical Laboratory could have any appreciable effect on this balance. Any significant pharmacologic action of such a solution must be mediated through some other mechanism. If it were intended to cause a shift in the equilibrium toward the acid side, it seems surprising that the parenteral route should have been used at all, J. B. S. Haldane²⁰ and others have shown that it is quite possible to produce marked changes of this nature by the oral administration of ammonium chloride, for instance.

The "1,000" Loeser solution examined by the A. M. A. Chemical Laboratory is about 0.008 normal and the "1,500" about 0.006 normal. Not only are these solutions greatly hypotonic, which alone could result in hemolysis on contact with blood, but according to Ponder²¹ it requires only a 0.002 normal solution of hydrochloric acid to produce destruction of erythrocytes. It appears, then, that at least one irreversible change in the blood stream which such solutions produce is laking of red cells passing the immediate vicinity of the needle point during the injection. In addition, changes would probably take place in the wall of the vein itself and might set up noxious reflexes²². Essentially the same effects, but possibly to a somewhat lesser degree might be expected from the injection of distilled water.

More than thirty years ago, it was claimed by Gilbert and Herscher²³ that the intravenous injection of distilled water in a dog produced a marked and lasting leukocytosis. The quantity of water injected (21 cc per kilogram) was much larger than the amounts of hydrochloric acid solution used clinically by Ferguson and others, but the changes induced in the blood stream are no doubt similar and probably differ only in degree. As was pointed out in *THE JOURNAL*²⁴ some time ago,

the effect produced is in all likelihood that of a non-specific protein, as the result of liberation of the contents of erythrocytes. Probably the humoral mechanisms of defense would thereby also be stimulated in addition to the mild leukocytosis that appears to occur, but this is purely conjecture. If the effect desired is that of the acid itself, assuming that there is some valid reason for choosing the intravenous route, it would seem preferable to dissolve the hydrochloric acid in physiologic solution of sodium chloride, if the effect is to be that of a hypotonic solution, plain distilled water should do practically as well. It is not recorded that either was tried by the propagandists for this form of therapy.

In the report of a special committee of the Council on Pharmacy and Chemistry on the status of intravenous therapy,²⁵ it was cautioned "all solutions [for intravenous use] should conform as closely as possible to the reaction of the normal blood" and "solutions should generally be nearly isotonic with the blood."

CLINICAL EVIDENCE

The clinical reports encompass a variety of different diseases that include practically the whole field of medicine. It need only be said of the clinical evidence reported so enthusiastically by Ferguson and his followers that it is uniformly uncontrolled. The simple and necessary expedient of retaining in each case a group of control patients similarly afflicted was apparently not used by any of the authors. In not a few of the cases, other treatment was used about the same time. Occasionally this was even specific or non-specific protein therapy,²⁶ in others the results reported, while apparently good, are no better than often occur with other treatments or even spontaneously. It is therefore quite impossible to judge whether or not the intravenous hydrochloric acid was responsible for the claimed clinical improvements.

CONCLUSIONS

It may be concluded that

1 The hydrochloric acid solution recommended for intravenous use is described in such terms that it may be of indefinite and variable composition.

2 In commercial specimens of the acid sold for this purpose by one firm, the acid content is too low to have any significant effect on acid-base equilibrium but it is present in concentration possibly sufficient to reinforce the hemolytic tendency of the distilled water in which it is dissolved.

3 Any alleged therapeutic effect in all likelihood is produced by alteration in blood colloids such as hemolysis.

4 It has not been demonstrated beyond reasonable doubt that an appreciable leukocytosis is produced by such injections.

5 The reputed causative relationship of the alleged leukocytosis to clinical improvement is derived entirely from so called *post hoc* reasoning and remains unproved.

6 Adequately controlled evidence of clinical benefit from such treatment is completely lacking.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary

TYPHOID VACCINE (See New and Nonofficial Remedies, 1933 p 391)

The National Drug Co., Philadelphia

Typhoid Vaccine (See New and Nonofficial Remedies 1933 p 394) Also marketed in three vial packages (one immunization), the first dose containing 750 million killed typhoid bacilli and the second and third doses containing respectively 1 500 million killed typhoid bacilli.

Typhoid Paratyphoid Combined Vaccine (See New and Nonofficial Remedies 1933, p 394) Also marketed in packages of thirty vials (ten immunizations) being ten sets of three doses the first dose containing 500 million killed typhoid bacilli and 250 million each of killed paratyphoid A and B bacilli the second and third doses containing respectively twice the number of bacilli in the first dose in packages of 150 vials (fifty immunizations) being fifty sets of three doses the first dose containing 500 million killed typhoid bacilli and 250 million each of killed paratyphoid A and B bacilli the second and third doses containing respectively twice the number of bacilli in the first dose.

ANTIRABIC VACCINE (See New and Nonofficial Remedies 1933, p 371)

The Gilliland Laboratories Inc., Marietta, Pa.

Rabies Vaccine Gilliland (Semple Method)—(See New and Nonofficial Remedies 1933 p 372)—Also marketed in packages of fourteen vials each containing 2 cc. The content of a vial is administered daily over a period of fourteen days.

VENTRICULIN (New and Nonofficial Remedies, 1933, p 264)

The following dosage form has been accepted.

Ventriculin 500 Gm Bottle

COD LIVER OIL (See New and Nonofficial Remedies 1933, p 271)

Ucoline Standardized Cod Liver Oil—Cod liver containing 0.5 per cent of a mixture of equal parts of oil of peppermint and oil of wintergreen as flavoring, and having a vitamin A potency of not less than 1000 units (U S P X) per gram and a vitamin D potency of not less than 333 units (A D M A) per gram.

Dosage—For adults 2 to 4 cc (30 to 60 minims) three times a day, for children 1 to 2 cc (15 to 30 minims) three times a day.

Manufactured by the Ucoline Products Co. Chicago. No U S patent or trademark.

Ucoline standardized cod liver oil complies with the standards of the U S P X. In addition it is required to have a content of fat soluble vitamin A as determined by the method of the U S P X of not less than 1000 units per gram and an antirachitic potency as determined by the method of the American Drug Manufacturers Association of not less than 333 vitamin D units per gram.

DEXTROSE (See New and Nonofficial Remedies, 1933, p 267)

The following dosage forms have been accepted.

Ampoule Sterile Solution Dextrose U S P 50 Gm. 100 cc Each ampule contains dextrose U S P 50 Gm in distilled water to make 100 cc.

Prepared by the E S Miller Laboratories Inc. Los Angeles

Ampoule Vial Sterile Solution Dextrose U S P 10 Gm 20 cc Each rubber capped vial contains dextrose U S P 10 Gm in distilled water to make 20 cc.

Prepared by the E S Miller Laboratories Inc. Los Angeles

Ampoule Vial Sterile Solution Dextrose U S P 25 Gm 50 cc Each rubber capped vial contains dextrose U S P 25 Gm in distilled water to make 50 cc.

Prepared by the E S Miller Laboratories Inc. Los Angeles

Ampoule Vial Sterile Solution Dextrose U S P 50 Gm 100 cc Each rubber capped vial contains dextrose U S P 50 Gm in distilled water to make 100 cc.

Prepared by the E S Miller Laboratories Inc. Los Angeles

EUCATROPINE (See New and Nonofficial Remedies, 1933 p 84)

Euphthalmine Hydrochloride—A brand of eucatropine-N N R

Manufactured by Schering Kahlbaum A G Berlin Germany (Schering & Glatz Inc New York distributor) U S patent 663 754 (expired) U S trademark 35 541

²⁵ Hunt Reid McCann W S Rowntree I G Voegtlin Carl and Eggleston Cary. The Status of Intravenous Therapy. J A M A 88 1798 (June 4) 1927

²⁶ Salter W M. Am Med 25 386 (June) 1910. Howell W I. Clin Med & Surg 39 653 (Sept) 1912

TABLETS COD LIVER OIL CONCENTRATE-LEDERLE—A cod liver oil concentrate in the form of sugar-coated tablets, each containing not less than 1,000 U S P units of vitamin A and not less than 500 A D M A units of vitamin D. This is equivalent in vitamin A potency to at least one-half teaspoonful, and in vitamin D potency, to at least one teaspoonful, of a cod liver oil containing at least 400 U S P units of vitamin A per gram and 133 A D M A units of vitamin D per gram.

Actions and Uses—Tablets cod liver oil concentrate-Lederle possess properties similar to those of cod liver oil so far as these depend on the fat soluble vitamin content of the latter.

Dosage—The dosage should be regulated according to the needs of the individual patient. The usual dosage for adults is two to three tablets after meals, for children, one to two tablets after meals.

Manufactured by the Lederle Laboratories Inc., Pearl River, New York. No U S patent or trademark.

The basic concentrate is obtained from cod liver oil by concentration of the unsaponifiable fraction of the latter. Each batch is assayed by the U S P method (weight and xerophthalmia) for its vitamin A content and by the A D M A method for its vitamin D content. Biologic assays are repeated on the finished tablets.

triETHANOLAMINE-CRUDE—A mixture containing approximately 75 per cent triethanolamine, $(\text{C}_2\text{H}_5\text{OH})_3\text{N}$, 20 per cent diethanolamine, $(\text{C}_2\text{H}_5\text{OH})_2\text{NH}$, and 5 per cent monoethanolamine, $\text{C}_2\text{H}_5\text{OH NH}$.

Actions and Uses—Triethanolamine-crude is an excellent emulsifying agent for use in the preparation of ointments and other dermatologic medicaments. When added to certain preparations used on the scalp, for example, oil of cade, it facilitates their subsequent removal. Triethanolamine-crude combines with fatty acids to form soaps with good detergent properties, which are soluble not only in water but also in gasoline, kerosene and oils. It is claimed to have the power of increasing the penetration of oily substances and to possess a certain amount of bacteriostatic action.

Dosage—In the preparation of emulsions, the fatty acids are dissolved in oil, and the triethanolamine-crude in water, after which the two solutions are mixed. Emulsions are made in concentrations of from 20 to 40 per cent, which may be diluted subsequently. For emulsions containing olive oil, the proportions are 2 per cent triethanolamine-crude to 15 per cent oleic acid. The same proportions are used for the majority of vegetable oil emulsions. For mineral oils, less fatty acid is required.

Triethanolamine crude is a colorless to pale yellow viscous hygroscopic liquid with a slight ammoniacal odor. It is miscible with water and alcohol and is soluble in chloroform. Immiscible with ether, benzene and purified petroleum benzine. The specific gravity is from 1.115 to 1.124 at 25°C. The refractive index is from 1.480 to 1.485 at 20°C.

To 1 cc. of triethanolamine crude add 0.1 cc. of copper sulphate solution, a deep blue color forms. Add 5 cc. sodium hydroxide solution and concentrate to $\frac{1}{3}$ volume by boiling; the color remains. To 1 cc. of triethanolamine crude add 0.3 cc. of cobalt chloride solution, a carmine red solution forms. In a test tube place 1 cc. of triethanolamine crude and by means of a slotted cork suspend a piece of moistened red litmus paper in the air space slot the side of the cork to let air escape, and place the tube in the steam bath; the paper turns blue. To 2 cc. of a 2 per cent aqueous solution of triethanolamine crude add 2 drops of phenolphthalein indicator solution, an alkaline reaction is indicated.

Transfer 50 cc. of triethanolamine-crude accurately weighed to a suitable Ladenburg distilling flask, attach the flask to a suitable condenser with receiver and slowly and carefully fractionate at a pressure of 10 mm. of mercury, not more than 8 per cent by weight of distillate is obtained below 89°C. of which 1 Gm. consumes not more than 15.4 cc. nor less than 14.3 cc. of normal hydrochloric acid when titrated as indicated for triethanolamine-crude, not more than 5 per cent by weight of residue is left after distillation below 209°C.

Transfer 2 to 3 Gm. of triethanolamine crude accurately weighed to an erlenmeyer flask. Add 75 cc. of water and 0.1 cc. of methyl red indicator solution and titrate with normal hydrochloric acid, not less than 6.7 cc. nor more than 7.8 cc. of normal hydrochloric acid is consumed per gram.

The weight of the ash obtained from 1 Gm. of triethanolamine crude accurately weighed is not more than 0.0001 Gm.

Transfer about 15 Gm. accurately weighed of triethanolamine crude to a 100 cc. beaker, add 50 cc. of solution A (dehydrated alcohol saturated with triethanolamine hydrochloride) and agitate the contents until the sample is dissolved. Add 10 cc. of solution B (100 cc. of solution A treated with dry hydrogen chloride until the weight increases 20 Gm.). Stir the contents well and set the mixture aside five minutes. Filter the solution through a prepared gooch crucible and complete transfer of the precipitate by washing with five to ten 1 cc. portions of solution A, then cover the precipitate by adding slowly 40 cc. of solution A, at the same time applying gentle suction to the crucible. Follow by washing with five 10 cc. portions of solution C (a mixture of 6 volumes of anhydrous ethyl ether and 4 volumes of dehydrated alcohol saturated with triethanolamine hydrochloride). Finally remove all liquid by suction, allow air to be drawn through the crucible for several minutes and dry to constant weight at 105°C. The weight of triethanolamine calculated from the weight of triethanolamine hydrochloride precipitate obtained is not less than 75 per cent of the weight of the sample.

Committee on Foods

THE COMMITTEE HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT
RAYMOND HERTWIG Secretary

NOT ACCEPTABLE

BALDINGER'S RAZAVA BREAD

(VALUABLE IN THE TREATMENT OF DIABETES, OBESITY AND CONSTIPATION)

H Baldinger and Company, St. Paul, submitted to the Committee on Foods a bread called Baldinger's Razava Bread, prepared from rye bran, shortening, salt and water without the use of any special leavening agent.

Analysis (submitted by manufacturer) —

	per cent
Moisture	56.9
Ash	1.9
Fat (ether extraction method)	1.8
Protein (N \times 6.25)	7.0
Starch (diastase method)	8.1
Crude fiber	2.6
Carbohydrates other than crude fiber (by difference)	29.8

Discussion of Label and Advertising—The first label submitted bore the statement "Valuable in the treatment of diabetes, obesity and constipation for diabetes and indigestion" and a number of testimonials of physicians recommending the bread for diabetes, dyspepsia and constipation. The company was advised that a label of this character was not compatible with the requirements of the Committee, whereupon proof for a revised label carrying the following statements was submitted:

Diabetics under the care of a physician will find that they can make provision for 2 or 3 slices of Razava Rye Bran Bread at every meal. You can eat 5 slices of Razava to 1 slice of any other bread if you wish to avoid fat producing foods.

It is not known whether this proposed new label was ever adopted, as the company has not replied to requests for information.

An advertising leaflet, "Eat Baldinger's Razava Bread," states:

In the treatment of diabetes The patient's whole difficulty lies in the fact that he cannot eat sugars and starches. For that reason the doctor prescribes very little or none of the foods that have a large amount of starch. These are mainly foods that contain wheat flour and potatoes. If the individual with diabetes must eliminate starches from his diet then the difference must be made up by eating more proteins and fat in order to satisfy his food requirement. Razava Bread and Razava Toast are particularly rich in these substances. Doctors prescribe at least two to three slices with each meal. Helps to reduce sugar. Several very good reasons why Baldinger's Razava Bread is truly a health builder and an excellent tonic for diabetes and constipation. Baldinger's Razava Diabetic Bread is rich in natural extract of free nitrogen protein and fat, contains practically every element of nutrition and highest form of nourishment the body needs in approximately right proportions. It has a tendency to regulate both Stomach and Intestinal digestion and therefore aids in the digestion of other foods. puts back into the diet the things that modern milling methods have taken out. is a natural food and produces a natural result. Purifies the blood. is recommended and used by physicians and hospitals for diabetes. is remedial and is in the highest sense a Diabetic Food.

The advertising states or implies that this bread is a specific cure for diabetes, indigestion and dyspepsia. Many of the claims are incorrect and misleading. Persons with diabetes can eat sugars and starches within their tolerances. Wheat flour and potatoes are not the "main foods" high in carbohydrate. The diabetic patient who "must eliminate starches" is not helped by the replacement of all starches or carbohydrates by proteins. Metabolized proteins may yield as high as 58 per cent carbohydrate in the form of dextrose. The claim that Razava Bread is "particularly rich" in fat and protein (which it is not) does not recommend the food for diabetic patients. Doctors in general do not prescribe "two or three slices" of Razava Bread "with each meal." The bread does not reduce sugar in the blood and is not a "health builder" or an "excellent tonic" for diabetes. The claim that "Razava Bread is rich in natural extract of free-nitrogen" is meaningless. The allegation "contains practically every element of nutrition and highest form of nourishment in approximately right proportions" is absurd and false. It does not "regulate stomach

and intestinal digestion," "aid in the digestion of other foods" or "put back into the diet the things that modern milling methods have taken out." A nutritionally important part of the wheat, the embryo, is not a component of Raza Bread. The statements "a natural food and produces a natural result" and "purifies the blood" are misleading vagaries, borrowed from quackery nostrum advertising. The product is not "truly a muscle builder." Allegations that the bread is "used by physicians and hospitals for diabetes" implies specific curative values not possessed. The bread is not "remedial" or "in the highest sense a diabetic food." The designation of a food as a diabetic food merely because it is low in carbohydrates is unwarranted and misleading and gives the erroneous impression that the food taken by diabetic patients in unrestricted quantities is harmless or that it has remedial action.

The advertising represents an attempt to exploit the diabetic or the dyspeptic patient by misinforming him of the true values of the bread or the proper treatment of these pathologic conditions. It promotes self diagnosis and self treatment by the sick who should be under the care of the physician. Advertising is incapable of prescribing the diet or treatment of the sick. Advertising of this character is a menace to public health.

The manufacturer was advised of the Committee's report but has ignored its recommendations and criticisms for correcting the advertising and labels. This product will therefore not be listed among the Committee's accepted foods.

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMULGATION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION. RAYMOND HERTWIG, Secretary.

CERTIFOODS CERTIFIED NURSERY FOODS— CARROTS (SIEVED)

VITAMIN CONTENT GUARANTEED, NO ADDED
SEASONING OR SUGAR

Distributor—Certifoods Inc., New York, a subsidiary of the Maltine Company, New York.

Packer—Curtice Brothers Co., Rochester, N. Y.

Description—Sieved carrots prepared by methods efficient for retention in high degree of the natural mineral and vitamin values, no added seasoning or sugar.

Manufacture—Fresh carrots are washed, blanched, mechanically peeled, inspected, trimmed by hand, again washed, diced, cooked with a small quantity of water in an atmosphere of live steam at 116 C, sieved in an atmosphere of nitrogen gas, canned, processed and packed as described for Certifoods Certified Nursery Foods—Green Beans (THE JOURNAL, Oct 3, 1931, p 1003). The processing is for forty minutes at 116 C.

An alternative is the use of carrots that have been previously diced, packed solid in No. 10 tins, covered with water, exhausted at 71 C, sealed and processed at 116 C for fifty-five minutes. The canned carrots before sieving are heated to 82 C, sieved in an atmosphere of nitrogen gas and subsequently treated as described above.

Analysis (submitted by manufacturer) —

Moisture	92.6
Total solids	7.4
Ash	0.5
Fat (ether extract)	0.1
Protein (N X 6.25)	0.6
Reducing sugars before inversion as dextrose	1.7
Reducing sugars after inversion as dextrose	3.7
Sucrose (copper reduction method)	2.1
Crude fiber	0.6
Carbohydrates other than crude fiber (by difference)	5.6
Calcium (Ca)	0.03
Phosphorus (P)	0.03
Iron (Fe)	0.0026

Calories—0.3 per gram, 9 per ounce

Vitamins—The methods of preparation, sieving and processing are efficient to conserve the natural vitamins in high degree.

The product is guaranteed to contain 350 units of vitamin A (Sherman method), approximately 1 unit of vitamin B (Chase and Sherman method) and 3 units of vitamin G (Bourquim and Sherman method) per ounce.

Claims of Manufacturer—See this section for Certifoods Certified Nursery Foods—Green Beans (THE JOURNAL, Oct 3, 1931, p 1003).

VAN CAMP'S PURÉED MIXED VEGETABLES WITH CEREAL AND BEEF BROTH

(ADDED SALT)

Manufacturer—Van Camp's, Inc., Indianapolis

Description—Blend of sieved carrots, peas, spinach, celery, potatoes, lima beans and tomato juice, with beef broth, rice and barley flours, slightly seasoned with salt, largely retains the natural minerals and vitamins.

Manufacture—Good quality carrots and potatoes are washed, peeled, finely cut and sieved in a steam atmosphere through a screen with openings of a size to produce the desired fineness and texture. Medium size canned peas and small green canned lima beans are similarly sieved. Fresh spinach, whenever available, is inspected, trimmed, washed, cut and sieved. If fresh spinach of high quality is not available, Van Camp's Pureed Spinach is used. Celery stalks are cleaned and ground to medium fineness. The tomato juice is prepared to retain largely its natural vitamin content (Van Camp's Tomato Juice, THE JOURNAL, Nov 28, 1931, p 1627). The beef broth per pint contains approximately the meat extractives from a pound of lean beef and a portion of bone. The beef broth, vegetables, barley and rice flours and salt in definite proportions are thoroughly mixed, heated and filled into enamel lined cans, which are sealed and processed.

Analysis (submitted by manufacturer) —

Moisture	per cent 85.0
Total solids	15.0
Ash	1.4
Sodium chloride	0.8
Fat (ether extract)	0.1
Protein (N X 6.25)	3.0
Reducing sugars as dextrose	1.0
Sucrose (copper reduction method)	0.5
Crude fiber	0.4
Carbohydrates other than crude fiber (by difference)	10.0
Alkalinity of ash	
(cc of normal acid per gram ash)	1.8
pu	5.7

Calories—0.5 per gram, 14 per ounce

Claims of Manufacturer—An easily digestible food for supplementing the infant milk diet, has a smooth consistency, and supplies bulk without roughness.

BEECH-NUT STRAINED PEAS

(SLIGHTLY SEASONED WITH SALT)

Manufacturer—Beech-Nut Packing Company, Canajoharie, N. Y.

Description—Sieved peas retaining in high degree the natural vitamin and mineral values, slightly seasoned with salt.

Manufacture—Illinois and Wisconsin peas are mechanically separated from the pods, cleaned, passed through a tank of cold water to float out any foreign matter, graded by machine, blanched in hot water at a minimum of time and temperature to prevent any significant leaching out of nutrients, inspected, canned, covered with hot brine, cooked in retorts, cooled and stored. The canned peas are strained, processed and packed as described for Beech-Nut Strained Carrots (THE JOURNAL, Nov 11, 1933, p 1562).

Analysis (submitted by manufacturer) —

Moisture	per cent 86.1
Total solids	13.9

SATURDAY, FEBRUARY 17, 1934

MENTAL EFFORT AND METABOLISM

In the Science of Nutrition, Graham Lusk stated that the source of mechanical work must be the metabolism, for mechanical energy cannot be derived from nothing. The necessary energy might be obtained in one of two ways: either at the expense of a proportionate reduction in the quantity of heat liberated by the resting organism or by an increase in the amount of the metabolism. In the former case, work would diminish the heat production and might cool the tissues, which is not observed to take place. If work were done at the expense of increased metabolism, and if this increase were completely converted into mechanical effect, the heat production in the organism might remain the same as in the resting state. If, however, the result of mechanical effort should be a stimulation of metabolism to the extent of not only enabling the body to do work but also causing it to produce more heat than when at rest, the tendency of the tissues would be to grow warmer, perhaps with a resulting outbreak of sweat to reduce the body temperature through physical regulation. The last named is the actual process.

The fact that under conditions of muscular exercise an augmented metabolism ensues is consonant with the early discovery of Lavoisier indicating an increased uptake of oxygen when work is done. What is to be said about the effects of mental effort? The influence of heightened mental activity on metabolism has long been debated. Muscular contraction, the fundamental feature of mechanical work by the organism, is attended with evidences of chemical changes. The output of carbon dioxide is increased, the intake of oxygen must sooner or later be augmented, heat production is an inevitable by-product. For many years it was impossible to demonstrate conclusively that such metabolic alterations attend the function of at least certain parts of the nervous system. With the development of more delicate methods of measurement, however, evidences of small changes indicative of metabolism seemed to be obtainable when peripheral nerves were provoked to manifest their characteristic functions. The nervous

structures constitute only a small part of the "active" tissues of the body, hence it is quite conceivable that relatively small chemical transformations would escape detection in estimations of the metabolism of the body as a whole.

The situation is well summarized in studies of the Benedicts¹ in the Boston Nutrition Laboratory of the Carnegie Institution of Washington on the metabolism during special types of mental effort by university trained subjects. The mental effort, continued for four consecutive fifteen minute periods, consisted chiefly in the multiplication of pairs of two digit figures. Before and following the mental effort, metabolism measurements were made with the subjects in complete mental repose or during "attention," the attention consisting of closing an electric contact whenever a white or a red light appeared in the field of vision. The metabolism was the same during repose and attention. Sustained, intense mental effort for one hour caused an increase in heart rate, a hardly measurable increase in respiration rate, a marked alteration in the character of the respiration, a considerable increase in the apparent total ventilation of the lungs, a small increase in the carbon dioxide exhalation, a smaller increase (on the average, 4 per cent) in the oxygen consumption and the heat production, and a slight increase in the apparent respiratory quotient. In the repose periods following mental effort all the factors measured, except in a few instances of physical discomfort or fatigue, were lower than during mental effort and tended to return to the original levels prevailing before the mental effort. The results of the second mental effort series on the same experimental day, duplicated for the most part those of the first. There was no indication of a summation effect or of a greater increase in the second series. Furthermore during the progress of the four consecutive fifteen minute periods of mental effort there was no evidence of any greater effect on the factors measured in the later periods. Skin temperature measurements on the forehead indicated that there was no appreciable alteration in the blood supply to the skin of the head. No change in the insensible perspiration during mental effort was noted. According to the Boston physiologists the small increases in oxygen consumption and heat production are in large part to be accounted for by the increased muscular activity accompanying the increased ventilation of the lungs and the increased heart rate.

On the basis of all these carefully established observations, one may well agree with the conclusion reached by the Benedicts that mental effort per se is without significant influence on the energy metabolism. Mental achievement therefore need not be curtailed because of the high cost of living—at least so far as calories are concerned.

THE PROBLEM OF DENTAL CARIES

Progress in the preservation of health and in the repair of bodily defects has in many instances involved change from empirical makeshifts to scientifically established prophylactic and curative procedures. Such innovations have gradually been introduced into the practice of medicine. They are destined to become equally prominent in dentistry. Dental caries, commonly known as decay of the teeth, has been called "the most prevalent disease of mankind." Evidence of its early appearance has been found in Egyptian mummies. It has been pointed out¹ that, since there has not been any known means of preventing the disease, dentists during the past hundred years or so have been endeavoring to the best of their ability to preserve the teeth by filling the cavities as they appear and by restoring the lost dental tissues with artificial substitutes. Dental caries is unique as a disease in several respects. There is no other pathologic process that even remotely resembles it. Dental caries is not comparable to caries of the bone. It is not a true necrotic process nor is it attended by inflammatory reactions in the affected tissues. It is characterized by the formation of progressive lesions in the teeth, simple decalcifications by acids formed locally as a result of the fermentation of carbohydrates by certain aciduric types of bacteria.

The teeth are remarkable in having "outer fortifications"—the enamel—that act as a protective agency. Harm usually comes from the exterior. When the protective layer of enamel is broken or otherwise disintegrated, the less resistant dentin underneath falls an easier victim to disintegrating forces. One reason why the problem of tooth decay has been approached in the past mainly from the reparative standpoint is that the enamel in particular was not supposed to be penetrable by fluids, whereas other structures of the body are in some sort of physiologic communication with the blood and lymph. From the point of view of the supposed "static" character of the enamel it is not easy to assume that the latter can be readily affected by the nutritive processes. The nonvitalistic theory of the nature of enamel and dentin is not universally accepted. The existence of "lymph channels" making it possible for the supposedly permanent calcareous structures to be affected by the blood is maintained by some dental investigators. Disintegration of tissue is a characteristic of certain degenerative diseases, hence in earlier years dental caries was considered to be a necrotic process resulting from inflammatory processes in the tooth itself. With the development of dental histology it became evident, in the words of Bunting,¹ that the dentin and enamel contain no circulatory systems capable of inflammatory reaction. Still, the old humoralistic idea remains even today, in the form of a belief by

many that the activity of dental caries is largely controlled by the hardness and softness of the teeth. The fact that clinical and experimental evidence has clearly shown that the activity of the disease is not necessarily related to the perfection of tooth structure, Bunting adds, seems not to have been universally grasped or its significance realized. The admonition "Feed your teeth" for the prevention of dental caries is still being heard, but the great majority of students in this field have agreed that the determinant causative factors in dental caries are not resident in the tooth itself.

In a review of some of the modern aspects of tooth preservation, THE JOURNAL has pointed out that the results of studies on children are at least unanimous in showing that efforts to provide an improved diet are in the main rewarded with increased resistance to tooth decay. This in itself is cause for gratification and should be an incentive to further study. Whether the prophylactic substance is one of the vitamins or some other factor, either known or as yet unrecognized, or even a combination of these in optimal amounts, must await future research.

If it is true that the enamel is not in direct contact with the circulation or the immunologic as well as nutritive and reparative factors thus provided, there remains the intermediation of the secretions of the salivary or mucous glands. Admitting, for the purpose of argument, that acid produced locally on the teeth by certain bacteria is the fundamental cause of the caries, its effective development might be determined by at least three features. These are, first, the chemical constituents of the salivary and oral secretions, second, the possible immunologic principles of the saliva, and, third, the character of the retained food debris remaining about the teeth. According to the conclusions of laborious researches at the University of Michigan,¹ whatever controlling influence the saliva may have on dental caries is not by virtue of its total calcium, total phosphorus or pH . Furthermore, in a correlated study of a small number of cases, no differences could be found in the total calcium, inorganic phosphorus, pH or carbon dioxide combining power of the blood. These observations, Bunting insists, strongly negate the hypothesis that dental caries is the result of low calcium or low phosphorus content of either the blood or the saliva or is due to a condition of acidosis, statements frequently made but unsupported by adequate scientific evidence.

The Michigan studies have demonstrated anew the occurrence of carious and noncarious groups of persons. Corresponding with this is the discovery that, contrary to the widely accepted view, *Bacillus acidophilus*, the active causative agency in dental caries, does not inhabit all mouths alike. In some persons the organism is totally absent and, when implanted repeatedly, does not grow but promptly disappears. In others

¹ Bunting, R. W. Recent Developments in the Study of Dental Caries. *Science* 78: 419 (Nov. 10) 1933. Many of the statements given above are taken from this paper.

it appears either intermittently or in small numbers. In persons in whom dental caries is active, as a rule, it grows luxuriantly and is constantly found on the teeth and in the saliva. Bunting reports that the intensive bacteriologic and clinical studies of thousands of cases over a period of five years by the University of Michigan group leave no room for reasonable doubt as to the specificity of *Bacillus acidophilus* as an active etiologic factor in dental caries. This view has been corroborated by the work of Rodriguez, Thompson and Enright. Acid fermentation and decalcification of teeth are thus firmly correlated. The amount and character of carbohydrate food debris in the mouth and about the teeth constitutes, therefore, an important factor in this dental disease. These studies are in harmony with prevalent expert opinion that the occurrence of dental caries is not determined by the structural quality of the tooth or by the degree of cleanliness of the mouth but that dental caries is definitely favored by certain phases of civilized life. There are other factors, such as hereditary constitution and general nutrition, that continue to deserve intensive research in relation to the welfare of the teeth. According to Bunting, at the present time the greatest promise for the ultimate solution of the problem seems to lie in the study of the chemistry of the saliva and its immunologic reactions against the organism of dental caries, and in a further study of diet in its relation to dental disease. To this end it is highly desirable that group studies be made in which the allied sciences of chemistry, nutrition, bacteriology and dentistry may be correlated in a truly scientific attack on this difficult and important problem in human welfare. It is only by studies of this broad nature, Bunting concludes, that any adequate concept of the nature of this disease or the means of its prevention may be attained.

ALPHA-DINITROPHENOL—A METABOLIC STIMULANT

A year has elapsed since alpha-dinitrophenol was introduced into therapeutics as a metabolic stimulant by Tainter and his collaborators of the Stanford University School of Medicine. In experimental animals, large doses of this chemical increase the metabolism as much as 1,200 per cent,¹ thus generating more heat than the animal can eliminate and resulting in fatal fever. Smaller doses increase the metabolism proportionately, without, however, any apparent deleterious effects on vital functions. Fat and carbohydrates are burned in about equal proportions with little if any effect on proteins. Particularly striking is a practically negligible effect on the circulation, in contrast to the

pronounced effects on this function from equivalent doses of thyroid.

In patients, the drug stimulates metabolism similarly to the increases that occur in animals, with little or no symptoms following subfebrile doses.² This metabolic stimulation is useful in the treatment of obesity,³ as shown by a fairly extensive series of cases. Particularly interesting is the fact that the drug appears to be effective regardless of the cause of the obesity, and even when the usual types of treatment are ineffective or inapplicable.³ However, dinitrophenol cannot replace thyroid secretion when this is definitely lacking.

Considering the potency of the drug, few untoward results or accidents have been reported. One death has occurred, that of a physician who took a total of 9 Gm in two doses, or about thirty ordinary daily doses.⁴ His dying statements left no doubt that the drug was not taken for therapeutic purposes but probably with suicidal intent. The only definite side-action from the therapeutic use of the drug is a skin rash, which occurs in about one out of every fifteen cases.⁵ The rash is uncomfortable for a few days and then disappears without sequelae. Even in the hands of a group that reported one case in which there was an unusually severe rash,⁶ the drug caused loss of weight in thirteen other cases in accordance with the general experience. There have been no deleterious effects observed so far on the kidneys, but rather the contrary.³ Likewise the liver appears not to be damaged.⁵ True, one suspected case of liver injury has been reported,⁶ but in this case the essential sign was a "jaundice," which, the physician failed to realize, might be only the color of the yellow dye he was administering. It is reassuring, therefore, that serious injury has not been demonstrated from therapeutic uses of this benzene derivative.

The introduction of dinitrophenol into therapeutics has aroused widespread interest in metabolic stimulants in general, and in substitutes for this drug, in particular. Already certain British workers⁷ are proceeding to test the therapeutic actions of a related cresol. From the limited evidence available, the British drug appears to be more cumulative than dinitrophenol and not to be as well tolerated in high doses. Its general order of activity is not, however, greatly different. No information is at hand on the frequency of undesirable effects from this cresol, nor is its clinical toxicity or efficiency established. Therefore the dinitrocresol is still in the experimental stage and not ready for general therapeutic use. In contrast, the past year's experience with dinitrophenol has shown it apparently to be a

relatively safe and reliable metabolic stimulant with which the practitioner may obtain therapeutic results. This does not mean that dinitrophenol should be given to every obese patient. In those cases in which diet has failed and thyroid is either not needed or not tolerated, dinitrophenol may be used with good prospects of benefit. However, as pointed out in the preliminary report of the Council on Pharmacy and Chemistry,⁸ this agent must be used only under carefully controlled conditions and with due regard for the possibility that more extensive use may bring to light as yet unsuspected toxic effect. Particularly, patients should be cautioned of the dangers of overdosage, its indiscriminate use by the public will undoubtedly lead to serious accidents.

Current Comment

POTENT BACTERIA-FREE VACCINE VIRUS GROWN ON CHICK EMBRYO MEMBRANES

Goodpasture and his co-workers¹ in the Vanderbilt University Medical School have shown that vaccine virus can be grown on the chorio-allantoic membrane of the chick embryo. These results have been confirmed with dermal strains of vaccine.² It now appears that this method can be used for the production of vaccine virus on a large scale.³ At present, vaccine virus is obtained from calves artificially inoculated on the skin of the abdomen, where the lesions of vaccinia or cowpox develop. The main objection to the calf virus is that it is not free from bacteria and other contaminants. In order to obtain absolutely pure virus, Goodpasture and Buddingh ground up embryo chick membranes, on which the virus was growing after inoculation with a dermal strain, and filtered the suspension through the Berkefeld N filter. The bacteria-free filtrate was centrifugated and the sediment inoculated on chick membranes, giving a pure strain of vaccine virus, which in fifteen months was carried through eighty-five successive generations in the chick without any intervening mammalian passage. Thus chick vaccine was found to have the same effects on rabbits and monkeys as the calf vaccine. In experiments on human beings with vaccine virus of the sixth and seventy-fifth chick membrane passage, after storage at 0 C for five months and three months, respectively, typical vaccinia lesions developed in the regular manner, the lesions being on the whole milder than those of the control inoculations with commercial calf vaccine virus. Revac-

inations with calf vaccine of the persons vaccinated with chick membrane virus and with the chick virus of the persons vaccinated with calf virus gave typical reactions of immunity in both groups. Further tests of the duration of immunity are under way. The advantages of the chick embryo vaccine virus over the calf virus appear to be the far greater ease of production and particularly freedom from contamination.

Association News

MEDICAL BROADCAST FOR THE WEEK

National Broadcasting Company

The American Medical Association broadcasts on a coast-to-coast network each Monday afternoon from 4 to 4 15, Central standard time (5 o'clock, Eastern standard time, 3 o'clock, Mountain standard time, and 2 o'clock, Pacific standard time). The subject for Monday, February 19, is "A Growing Menace." The speaker will be Dr W W Bauer, director, Bureau of Health and Public Instruction.

Columbia Broadcasting System

The Association broadcasts on a western network of the Columbia Broadcasting System each Thursday afternoon on the Educational Forum from 4 30 to 4 45, Central standard time. The subject for Thursday, February 22, is "Some Popular Health Delusions." The speaker will be Dr Bauer.

Radio Talk from Station WBBM

The Association broadcasts on Tuesday mornings from 8 55 to 9 o'clock, Central standard time, over Station WBBM (770 kilocycles, or 389 4 meters). The subject for Tuesday, February 20, is "Freak Accidents."

CALIFORNIA

Discussion of Amebiasis—The San Francisco County Medical Society devoted its meeting, February 13, to a discussion of amebiasis. Speakers were Dr Jacob C Geiger, city health officer, on "Public Health Aspects of Amebiasis," Dr Alfred C Reed, "Clinical Amebiasis," and Chauncey D Leake, Ph D, "Chemotherapy of Amebiasis."

Outbreak of Typhoid—Fifty-one cases of typhoid with three fatalities were reported in a recent outbreak in Santa Barbara and vicinity. Most of the patients were hospitalized, but many have now been released from quarantine. Members of the state department of health and the U S Public Health Service assisted in the search for the source of the epidemic, which was not determined. No cases with date of onset later than December 7 have been reported.

Personal—Dr William F Stein, Fresno, became health officer of Fresno County, January 16, succeeding Dr James E Pendergrass, Clovis.—Dr Alfred C Reed, professor of tropical medicine, University of California Medical School, San Francisco has been appointed consultant in that specialty to the San Francisco Department of Health.—Dr Ernest C Foster has been appointed health officer of Kings County, succeeding Dr Cecil G Newbecker.—Dr Palmer D Miller has been named health officer of Dinuba, in Tulare County, to succeed Dr Charles S Mitchell.—Dr James L Faulkner, Red Bluff, has been appointed health officer of Tehama County, succeeding Dr Ernest E Thompson.

COLORADO

Annual Registration Due March 1—All practitioners of medicine and surgery holding licenses to practice in Colorado are required by law to register annually before March 1, with the secretary-treasurer of the Board of Medical Examiners, and to pay a fee of \$2, if a resident of Colorado, or \$10, if a nonresident. Failure to pay this fee within the time stated automatically suspends the right of a licensee to practice while delinquent. If he nevertheless continues to practice, he is subject to the penalties provided by law for practicing medicine without a license. Failure to pay this fee for three consecutive years results in the automatic cancellation of a delinquent practitioner's license to practice.

Institutional Advertising—A resolution has been adopted by the board of councilors of the Colorado State Medical Society which states the attitude of the society toward members who are associated with institutions that advertise for or solicit the patronage of the public. It was pointed out that while the society cannot maintain direct control of the hospitals and sanatoriums guilty of unethical advertising this coming under the jurisdiction of the Colorado Hospital Association, it can exclude from membership those physicians who are affiliated with them. The resolution became effective on its publication in the February issue of *Colorado Medicine*. The Colorado Hospital Association December 28 adopted a code of ethics to govern the practice of hospitals in relation to one another, advertising, rights of patients and public health programs. This code went into effect immediately.

DISTRICT OF COLUMBIA

Dr Patterson Honored—An honorary membership in the American Academy of Ophthalmology and Otolaryngology was presented to Major General Robert U. Patterson at the Army and Navy Club in Washington Nov. 21, 1933. Dr. Burt R. Shurly, Detroit, was toastmaster at the banquet and speakers in addition to Dr. Patterson, included Surg. Gen. Perceval S. Rossiter, U. S. Navy, and Drs. Harris P. Mosher, Boston, and William Thornwall Davis. Dr. Patterson was presented with a silver platter.

Medical Bills in Congress—S. 2006 has passed the Senate authorizing the Commission on Licensure to Practice the Healing Art in the District of Columbia to license Della D. Ledendecker to practice chiropractic notwithstanding the provision in the healing arts practice act requiring applications from candidates for licenses to practice chiropractic to be filed within ninety days from the date of the approval of the act provided that Della D. Ledendecker shall otherwise be found by the commission to be qualified to practice under the provisions of the act.

Second Graduate Clinic—The George Washington University School of Medicine will conduct its second annual graduate clinic, February 23-24. Sessions will be held in the Gallinger Municipal Hospital, University Hospital and the medical school. The program includes a symposium on jaundice by Drs. Charles S. White, Walter A. Bloedorn and Edward B. Vedder, and one on cystostomy and ureterography by Drs. Claude Moore, Lyle M. Mason, Miles P. Omohundro, Thomas C. Thompson and Gilbert Ottenberg. Under the classifications of demonstrations, ward rounds and clinics the following subjects among others, will be treated:

Psychological Factors in Disease Dr. William A. White
Leukemia, Endocrine Disorders Dr. Stuart O. Foster
New Growths of the Colon Drs. Archibald I. Riddick and William W. Chase
Surgery in Sterility of Women Dr. Jacob Kotz
The Present Status of Serum Therapy Dr. George W. McCoy, director of National Institute of Health
Amebic Dysentery Drs. Vedder, Roger M. Choisser and Herman S. Hoffman
Use of Galactose in Diabetic Patients Joseph H. Roe, Sc.D. and Dr. John A. Reed

GEORGIA

Prizes Awarded—At the twenty-ninth annual meeting of the Fulton County Medical Society, January 4, the Dr. L. C. Fischer Awards for 1933 were presented. For the best original research, one prize went to Drs. James Fletcher, Hanson, William K. Purks and Ruskin G. Anderson for "Electrocardiographic Studies of the Dying Human Heart." For their paper on "Congenital Heart Block," Drs. Launcelot Minor Blackford and Henry M. McGehee were awarded a second prize for the best written paper. These prizes have been offered for several years by Dr. Fischer to "stimulate original and research work." Papers must be presented before the society before being submitted for consideration in the contest.

ILLINOIS

Abortionist in Penitentiary—Sherman T. Lewis, alias J. C. or J. G. Littlefield, formerly of Chicago, is now serving a sentence of fourteen years' imprisonment in the Illinois Penitentiary, Joliet, having been convicted of murder by abortion. Although a 1892 graduate of Northwestern University Medical School, Lewis was practicing without a license in Illinois. He was licensed in Wisconsin, but his license was revoked, April 17, 1928, following a conviction of manslaughter. He had been acquitted of a previous charge of manslaughter growing out of an alleged illegal operation, it was reported. He had also been licensed to practice in Nevada and Colorado.

Increase in Laboratory Tests—There were 171,638 tests made for all diseases in the diagnostic laboratories of the state department of public health in 1933 as compared with 162,325 in 1932. Of these, 25,856 were positive in 1933 and 24,727 in 1932. The number of specimens examined for tuberculosis totaled 17,395 last year as compared with a previous figure of 15,033, and the proportion of positive tests increased from 15 to 17 per cent. More specimens were examined for diphtheria and typhoid in proportion to cases reported than ever before, but the percentage found positive was lower. Tests of animal heads for rabies went up from 505 in 1932 to 611 last year and the proportions found positive were 35 and 45 per cent, respectively. Of the 99,352 specimens examined for syphilis, 17,630 were positive, an increase of 2,697 in the number of tests made for this disease.

Chicago

Society News—Speakers before the Chicago Gynecological Society, February 16, were Drs. Henry Schmitz on "Treatment of the Bleeding Uterus Due to Benign Lesions with Radium and Roentgen Rays," William C. Danforth, Evanston, Ill., "Treatment of Fibroids: Report of a Series of 443 Cases," and David S. Hills, "Fibroids in Pregnancy."—"The Emotional Difficulties of Unemployed Women" was the subject discussed at a meeting sponsored by the Illinois Society for Mental Hygiene, February 16, by Dr. David B. Rotman, Dr. Douglas G. Campbell and Ruth O. Potter, social worker.—"The Chicago Society of Allergy will be addressed February 19, among others, by Dr. Milton B. Cohen, Cleveland, on 'The Mechanism of the Asthmatic Attack in Allergic Asthma'."—Dr. Hilmer William Elghammer will address the Chicago Pediatric Society, February 20, among others on "Erythrocyte Sedimentation Rate in Rheumatic Infection."—At a meeting of the Chicago Urological Society, February 21, the speakers will include Dr. John Talbot Gernon on "A New Antigen in the Treatment of Gonorrhea."

INDIANA

Society News—At a meeting of the Floyd County Medical Society in New Albany, January 8, Dr. Harry E. Voyles spoke on "The Use of Insulin in the Nondiabetic Malnourished Patient."—Dr. Thurman B. Rice, Indianapolis, discussed public health before the Adams County Medical Society in Decatur, January 12.—"The Tippecanoe County Medical Society was addressed in Lafayette January 12, by Drs. Oscar N. Torian and Joseph W. Ricketts, Indianapolis, on "Colds and Their Complications in Children" and "Amebic Dysentery," respectively.—"Dr. James O. Beavis, Dayton, Ohio, discussed 'Harelip and Cleft Palate' before the Wayne-Union Counties Medical Society in Richmond, January 11."—At a meeting of the Elkhart County Medical Society in Elkhart, January 4, Dr. Orus R. Yoder, Ypsilanti, spoke on "The Psychological Management of the Patient."—Dr. Ernest R. Carlo, Fort Wayne, addressed the Northeastern Indiana Academy of Medicine, January 25, on "Pneumonia in Children."—A medico-legal symposium constituted the meeting of the Indianapolis Medical Society, January 9, with Mr. Alfred E. Evans of the Indiana University School of Law discussing compensation laws and Mr. Albert Stump, expert testimony.

KENTUCKY

Society News—A symposium on amebiasis will be presented before the Jefferson County Medical Society, Louisville, February 19, by Drs. Morris Flexner, Herbert H. Hagan and Harry S. Frazier. A discussion of public health plans and policies was presented at a meeting, February 5, by Drs. Arthur T. McCormick, Hugh R. Leavell and John D. Trawick, health commissioner of the state city and county, respectively.

Bills Introduced—S. 204 and H. 428 propose to reorganize the executive branches of the state government. Among other things, these bills propose to create a Department of Health to "exercise all administrative functions of the State."

in relation to food and drug control, sanitation and vital statistics, the appointment and control of County Board of Health, the prevention and control of communicable diseases. The State Board of Health, the Board of Chiropractic Examiners, the Board of Dental Examiners, the Kentucky Pharmaceutical Association and the Board of Pharmacy are to be deemed to be included within the Department of Public Health and constitute parts thereof, but each of said boards shall continue to exercise all the powers rights and functions with relation to their respective professions."

LOUISIANA

Personal—Sir Aldo Castellani, director, Ross Institute of Tropical Hygiene, London School of Hygiene and Tropical Medicine returned to New Orleans recently to begin his duties at Louisiana State University Medical Center as professor of tropical medicine, he will spend part of each year at the university.

Society News—At a joint meeting of the staff of the Baptist Hospital and the New Orleans Gynecological and Obstetrical Society, November 28, with members of the Second District Medical Society as guests, the speakers included Drs Henry B Alsobrook on 'Extra-Uterine Pregnancy Complicated by Intestinal Obstruction,' and John T Sanders, Bicornuate Uterus with Twin Pregnancy. The Fifth District Medical Society was addressed in Monroe, December 1, by Drs Victor Carey on "Cultural, Spiritual and Material Medicine" and Fred Rankin, Lexington Ky 'Diagnosis and Surgical Treatment of Cancer of the Colon and Rectum'. Dr Melville W Hunter, Monroe, also spoke. Speakers before the East and West Feliciana Bi Parish Medical Society in Clinton in December were Drs James M Bamber, New Orleans, and Carl A Weiss, Baton Rouge, on "Arteriosclerotic and Hypertensive Heart Diseases" and "Commoner Diseases of the Eye and Their Relation to General Systemic Diseases," respectively.

MAINE

Clinical Meeting—The staff of the Eastern Maine General Hospital, Bangor, will present a clinical program for the Maine Medical Association, February 20-21, consisting of clinical case demonstrations, ward walks and surgical operations. There will be no papers. On the evening of February 20 the state association will meet jointly with the Penobscot County Medical Society.

Society News—At a meeting of the Portland Medical Club, December 5, Dr Arthur Paul Wakefield Fairfield spoke on 'Public Health in China and the United States'. Speakers before the Kennebec County Medical Association at Augusta, December 21, were Drs Samuel H Kagan, Augusta and John O Piper, Waterville, on 'Massage and Mobilization in the Treatment of Recent Injuries and Spontaneous Meningeal Hemorrhage,' respectively.

MARYLAND

Society News—Speakers before the Maryland Academy of Medicine and Surgery, recently, were Drs Albert S Hyman, New York and Walter E Dandy, Baltimore on 'Coronary Arterial Disease and Its Treatment' and 'Lesions of the Cranial Nerves,' respectively. Justin M Andrews, Sc D, associate professor of protozoology, Johns Hopkins School of Hygiene and Public Health, addressed the Baltimore City Medical Society, January 5, among others on 'Epidemiology and Control of Amebiasis'. At a meeting of the Caroline County Medical Society, December 14, Dr Henry V Wilson, Jr, Dover, spoke on 'Surgical Considerations of Gallbladder Disease'.

DeLamar Lectures—Warder C Allee, Ph D, professor of zoology, University of Chicago, opened the current series of DeLamar Lectures in Hygiene at Johns Hopkins University School of Hygiene and Public Health, December 19, with a talk on 'Recent Studies in Experimental Populations'. Speakers and their subjects comprising this series are as follows:

- Dr James Ewing, professor of oncology, Cornell University, 'The Prevention of Cancer', January 9.
- Dr Mark F Boyd, field director, International Health Division, Rockefeller Foundation and director station for malaria research, Tallahassee, Fla., 'Research Opportunities Provided by Naturally Induced Malaria Therapy', January 16.
- Dr Waller S Leathers, dean, Vanderbilt University School of Medicine, Nashville, Tenn., 'An Investigation of Hookworm Disease in a Southern State', January 31.
- Dr Lewis W Hackett, assistant director, International Health Division, Rockefeller Foundation, 'New Light on the Epidemiology of Malaria', February 20.
- Robert Spurr Weston, Boston, sanitary engineer, 'Recent Developments in the Art of Water Purification', March 6.
- Dr Earl B McKinley, dean, George Washington University School of Medicine, Washington, D C, 'Etiology of Leprosy', March 20.

MASSACHUSETTS

Dr Washburn Becomes Commissioner of Institutions—Dr Frederic A Washburn, who recently resigned as superintendent of the Massachusetts General Hospital, Boston, after holding the position since 1922, will become commissioner of institutions of Boston, effective March 1. He will have jurisdiction over the Hospital of the Chronic Sick and the Alms House at Long Island, child welfare, placing of children in foster homes, and the registration of the insane.

Memorial to Dr Kline—In tribute to the memory of Dr George M Kline, commissioner Massachusetts State Department of Mental Diseases, from 1916 until his death last year, an oil portrait of him has been placed in the administration building of the new Metropolitan State Hospital, Waltham. In addition, the trustees of the hospital have named the assembly building in the new institution the Kline Memorial Hall and an inscribed bronze tablet will be placed at the entrance to commemorate his services to the hospitals and schools of the department of mental diseases. An enlarged photograph of Dr Kline has also been presented to each of the sixteen institutions of the department.

MICHIGAN

Personal—Henry F Vaughan, Detroit, Dr P H was made an honorary member of the St Louis Medical Society, December 19, at a meeting which he addressed on the Detroit plan. Dr Vaughan is a native of Missouri. Dr Charles A Neafie, formerly health officer of Pontiac, has been appointed medical director of Pontiac General Hospital. Dr Don W Gudakunst, Detroit, was named president of the newly organized Michigan Association of School Physicians, Nov 10, 1933.

Dr Jennings Honored—The Wayne County Medical Society will give a dinner, February 28 at the Book-Cadillac Hotel, Detroit, in honor of Dr Charles G Jennings, Detroit, who has completed more than fifty years in the practice of medicine. Dr Walter R Parker, Detroit, will be toastmaster and Hon James O Murfin, former judge of the circuit court of Wayne County, will be a speaker. Dr Jennings graduated from the Detroit Medical College in 1879. He was professor of medicine and chief of the department at his alma mater from 1897 to 1917. He was president of the American Pediatric Society in 1904 and of the American Therapeutic Society in 1922.

Plan for Medical Service for Unemployed—Under a plan authorized by the Federal Emergency Relief Administration, a Medical-Dental Bureau has been established in the headquarters of the Wayne County Medical Society, which furnishes the services of physicians, dentists, pharmacists and nurses to unemployed welfare patients. William J Burns, executive secretary of the Wayne County Medical Society, has been named head of the bureau. Cooperating agencies are the medical society, the Detroit District Dental Society, Detroit Nurses Association and the Detroit Pharmaceutical Association. Home and office care is provided for unemployed persons on welfare rolls but does not include hospitalization. A switchboard has been installed in the society's headquarters, and a clerical staff added to handle this service. According to the plan, the patient gets in touch with his family physician, who telephones the bureau for an authorization, which is given verbally and subsequently sent to him through the mail. All authorizations are limited to emergency service, the relief of pain and treatment of acute conditions.

MISSOURI

Clinics Award—The St Louis Clinics will offer an award of \$100 and a certificate to the member of the St Louis Medical Society presenting the best paper before the latter during the coming year. The competition opened January 1 for one year. The presentation will be made at the Clinical Conference of the St Louis Clinics in 1935, which will probably take place in May.

Cancer "Specialists" Assessed Damages—Two St Louis physicians were ordered to pay damages of \$6,500 in November as the result of a suit brought by the husband of a woman who died in 1931, following nine months' treatment with a so called cancer paste. It is reported Drs Edward C and John E Westaver, father and son, graduated from the St Louis College of Physicians and Surgeons in 1898 and 1918, respectively. This institution's charter was revoked in 1927 on a charge of being a diploma mill. The recent case was tried before a jury, which gave a unanimous verdict. The physicians promised a cure with their salves charging \$2 a treatment. It

was stated. Members of the state medical association testified that 'the 'paste' was a futile effort to cure real cancer but might heal certain kinds of noncancerous tumors and sores'.

Hodgen Memorial Unveiled—A bronze plaque was unveiled in the building of the St. Louis Medical Society, January 9, as a memorial to Dr. John T. Hodgen. It is the work of Malvina Hoffman, sculptress, and is the gift of the St. Louis Surgical Society and the Medical Fund Society. The plaque was unveiled by Dr. Hodgen's grandson, Dr. John T. Hodgen of Grand Rapids, Mich., who is an honorary member of the surgical society. This ceremony followed the presentation of the annual Hodgen lecture by Dr. Walter B. Cannon, George Higginson professor of physiology, Harvard Medical School, Boston, on "Significance of the Emotional Level." The lecture is sponsored by the Surgical and the Medical Fund societies which were established in 1891 and 1872 respectively. Dr. Hodgen died about fifty years ago.

NEW JERSEY

Bills Introduced—S. 94, to amend the law providing liens in certain cases for hospitals, proposes to raise to 50 cents the fee required to be paid on filing a claim of lien. A. 115 proposes to authorize any judge, either on his own motion or on the motion of counsel to appoint one or more expert witnesses not exceeding three, to examine and investigate, and to testify relative to, matters as to which such expert evidence will be required. A. 125, to supplement the pharmacy practice act, proposes to authorize courts to issue injunctions to restrain the unlicensed practice of pharmacy. A. 126 to supplement the pharmacy practice act, proposes to provide for the suspension or revocation of a license to practice pharmacy if the holder has been convicted of a crime involving moral turpitude. A. 132 proposes that nothing in the state emergency relief act shall be construed to prohibit or limit any licensed physician occupying a position as a state, county, municipal or school physician from being compensated by the state for the care and treatment of emergency relief patients.

NEW YORK

Bills Introduced—S. 348 proposes to make it unlawful for any person to give any false police alarm or false call for a physician or hospital. S. 505, to amend the provisions of the medical practice act with respect to the licensing of physiotherapy technicians, proposes to permit any person engaged in the practice of physiotherapy prior to May 17, to be licensed without examination, to practice physiotherapy if he is a graduate of a legally chartered school or college of physical therapy. S. 514, to amend the law providing exemption from the payment of registration fees for hospital ambulances, proposes that such exemption shall extend only to ambulances used exclusively to carry sick or injured persons. A. 490 and A. 561 propose to create a board of barber examiners and to regulate the practice of barbering. A. 570, to amend the workmen's compensation act, proposes, in effect, to make compensable all occupational diseases arising out of any employment covered by the act.

New York City

Afternoon Lectures at the Academy—Recent afternoon lectures in the series at the New York Academy of Medicine were:

Dr. Abernethy Benson Cannon December 22 Early Diagnosis and Treatment of Syphilis
Dr. Edwin Beer January 5 Calculous Disease of the Urinary Tract
Dr. Maximilian A. Ramirez January 12 Newer Work in Allergy of Interest to the General Practitioner
Dr. John H. Wyckoff January 19 The Tachycardias: Diagnosis and Treatment
Dr. George R. Minot Boston January 26 The Anemias—Etiology and Treatment

Hospital Doubles Number of Patients—The annual report of New York Hospital covering the year 1932 made public January 2, showed that the number of patients doubled after the hospital moved into its new quarters in September 1932. In that month the hospital had 5,901 pavilion patients and 663 private patients, in October the pavilion patients had increased to 12,118 and private patients to 1,372. Outpatients increased from 10,825 in September to 17,425 in December. The report stated that 38 per cent of the ward service and 39 per cent of the outpatient service were rendered free.

Health Report for 1933—The lowest death rate in the history of New York, 10.23 per thousand of population, was reported by the department of health in its report for 1933. There were 75,153 deaths, of which the largest number 18,667, were caused by diseases of the heart. Other important causes were pneumonias 7,679 deaths, cancer, 8,929 tuberculosis 4,057 Bright's disease, 3,639 accidents all forms 4,234 and

diabetes, 2,139. A new low death rate for tuberculosis was registered, 55.21 per hundred thousand, in 1928 this rate was 69.12. During the year there were only 1,895 cases and 83 deaths from diphtheria, a result attributed to the department's intensive campaign of immunization. There were 588 cases of typhoid with 70 deaths, most of which resulted from bathing in polluted waters or eating shellfish taken surreptitiously from forbidden areas. Automobile accidents caused 1,135 deaths, a record low rate of 15.45 per hundred thousand. Diabetes, with a rate of 29.1, showed a notable increase since 1928, when the rate was 24.8. The suicide record showed improvement with 1,325 or a rate of 18.04, as compared with 1,595, a rate of 22.1 for 1932. The infant mortality rate was 53.2 per thousand births, an increase over 1932, when the rate was 50.91. Maternal mortality was 6.41 per thousand live births, as compared with 6.09 in 1932 and 5.29 in 1928.

NORTH CAROLINA

Personal—Dr. Crete N. Sisk, Henderson, has been appointed health officer of Vance County to succeed Dr. Clarence H. White, who resigned to spend a year at Harvard School of Public Health under a fellowship from the Rockefeller Foundation.

Society Establishes Award—The Guilford County Medical Society at its December meeting in High Point voted to establish an annual award of a silver cup and a complimentary dinner to be given to the member who has produced during the year an exceptionally creditable piece of work related to the medical sciences. A committee was to be elected to select the recipient of the award. At this meeting Dr. Paul P. McCam Senatorium addressed the society on early diagnosis of tuberculosis by the roentgen ray.

The Control of Psittacosis—The state board of health December 5, promulgated regulations governing methods of controlling psittacosis. It is ordered that cases of psittacosis must be reported within twenty-four hours and that patients must be isolated. Among other things, persons exposed to the disease should be kept in quarantine five days and under observation for three weeks. It is advised that all birds be regarded as potentially dangerous when they have been exposed and be kept under quarantine. Shipment of birds into the state must conform to federal regulations.

OKLAHOMA

Special Health Projects—Three public health projects are now under way in Oklahoma under the auspices of the state health department in addition to its regular program of disease prevention. Under the direction of sanitary engineers, fifty-two drainage projects to eliminate breeding places of malaria mosquitoes are in progress, and others are being prepared. For this work 3,500 men are being furnished by the Civil Works Administration. One hundred and ninety community sanitation projects have been approved and about 1,600 men are employed on them. The third is a state-wide immunization campaign against diphtheria, typhoid and smallpox, in which the vaccines are furnished by the board to any physician in the state. It is estimated that about 200,000 children have been immunized against diphtheria. The number immunized against typhoid and smallpox will be smaller because of previous work in this field, according to Dr. George N. Bilby, Oklahoma City, state health officer.

Society News—The Southeastern Oklahoma Medical Association met in Durant, December 14 with the following speakers among others: Drs. Leonard S. Willour, McAlester, 'Organized Medicine'; George W. West, Eufaula, 'Defects in Medical Education'; and Forrest P. Baker, Tahlequah, 'Tuberculosis in Childhood'.—Members of the staff of General State Hospital, Norman addressed the Okmulgee County Medical Society, December 18 as follows: Drs. James J. Gable, on "Acute Neurasthenia"; Charles R. Rayburn, "Circulation of the Central System"; and John L. Day, "Mental Hygiene".—Speakers at the meeting of the Southern Oklahoma Medical Association at Shawnee, December 5, were, among others: Louis A. Turley, Ph.D., Norman, "Pathology of Encephalitis"; Drs. John B. Morey, Ada, "Circulatory Diseases of the Extremities"; and Carl T. Steen, Norman, "The Mental Hygiene Movement".—Dr. Floyd S. Newman, Shattuck, addressed the Woodward County Medical Society, Woodward, December 15 on blood transfusion.—Drs. Everett F. Jones and John R. Reagan, Wichita Falls, Texas, addressed the Jefferson County Medical Society, Waurika, December 4 on "Ten Years' Experience with Radium in Uterine Conditions" and "Electrical Treatments for Prostatic Conditions," respectively.

PENNSYLVANIA
Philadelphia

Students Want Health Service Abolished—The *Daily Pennsylvanian*, student publication of the University of Pennsylvania, in a recent editorial recommended that the student health service of the university be abolished. The editorial stated, it is said, that the situation seems to be without remedy, that students cannot boycott the health service because the charge is prorated on their bills each semester no matter what their wishes. The charge to students is said to be \$10 a year, \$5 a semester.

Hospital News—The Women's Homeopathic Hospital celebrated its fiftieth anniversary, October 27—Dr Morris B. Cooperman will give a public lecture at Mount Sinai Hospital, February 28, on "Backache and Flat Feet," one of a series of nine health talks—Jefferson Hospital has become a member of the Circulating Picture Club of the Philadelphia Art Alliance. It is said to be the first institution of its kind to take advantage of the lending library of paintings to be hung in sickrooms and convalescent wards.

Personal—Dr Charles A. E. Codman was elected president of the Medical Club of Philadelphia, January 19—Dr and Mrs John M. Barthmaier celebrated their fiftieth wedding anniversary, January 8—Dr Randle C. Rosenberger reports that a valuable Stradivarius violin has been stolen from his office at Jefferson Medical College—Dr Charles A. Moriarty has been appointed a coroner's physician—Dr Morton McCutcheon was recently elected president of the Pathological Society of Philadelphia, and Herbert L. Ratchiffe, Sc.D., secretary.

TEXAS

Society News—Dr Claude C. Cody, Houston, was elected president of the Texas Ophthalmological and Otolaryngological Society at its annual meeting in Dallas, December 8-9, and Dr Oscar M. Marchman, Dallas, secretary. Among speakers were Drs Harry S. Gradle, Chicago, on "Evaluation of So Called Ophthalmic Advances," James B. Costen, St. Louis, "Conditions of the Jaw," and Lieut. Col. George R. Callender, Fort Sam Houston, "Malignant Tumors of the Eye." The next session will be held in San Antonio, in connection with the meeting of the Southern Medical Association—Dr Walter B. Reeves, Greenville, was elected president of the North Texas Medical Association at its semiannual meeting in Dallas, December 5-6. The June meeting will be held in Terrell.

Health at El Paso—Telegraphic reports to the U. S. Department of Commerce from eighty-six cities with a total population of 37 million for the week ended February 3, indicate that the highest mortality (215) appeared for El Paso, and the rate for the group of cities as a whole, 123. The mortality rate for El Paso for the corresponding period last year was 172, and for the group of cities, 121. The annual rate for eighty-six cities for the five weeks of 1934 was 125, as against a rate of 129 for the corresponding period of the previous year. Caution should be used in the interpretation of these weekly figures as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have a large Negro population may tend to increase the death rate.

VIRGINIA

Bills Introduced—H. 23 to amend the optometry practice act, if enacted apparently would make it unlawful for physicians to prescribe lenses or ocular exercises for the correction or relief of any ocular refractive deficiency or deformity, or visual or muscular anomaly of the human eye. A bill introduced in the House of Delegates, February 6 by Mr. Scott and referred to the Committee on General Laws proposes to amend the law making it unlawful for any tobacco manufacturer to employ opium, either in the tobacco used or in the paper wrappers of cigarettes, by forbidding also the like use of marihuana, loco weed or any other sedative, narcotic or hypnotic drug, like chemical or substance.

WEST VIRGINIA

Society News—Dr Cyrus C. Sturgis, Ann Arbor, Mich., addressed the Ohio County Medical Society, Wheeling, January 19, on "Diagnosis and Treatment of the Macrocytic Anemias." Dr Porter P. Vinson, Rochester, Minn., addressed the society, January 5 on diagnosis and treatment of cardiospasm—Dr Russell B. Bailey, Wheeling, addressed the Marshall County Medical Society, January 9 on cancer of the breast.

—Dr William V. Wilkerson, Montgomery, addressed the Fayette County Medical Society, Oak Hill, December 12, on neurologic diagnosis.

Rural Sanitation Program—Dr Frederick T. Foard, Jr., of the U. S. Public Health Service, has been assigned temporarily to the West Virginia State Department of Health to assist in the organization and supervision of a state-wide rural sanitation program. The plan, which is being carried out by the health department in cooperation with the Public Health Service and the Civil Works Administration, has as its objective improvement of sanitary conditions in all farm homes and homes at mining camps. About 3,000 men are already at work and it is expected that about 8,000 will be employed on the project by March 15.

WISCONSIN

Personal—Dr George H. Conklin, Superior, has been selected as superintendent of the Douglas County tuberculosis sanatorium—Dr Harry Beckman, professor and director of the department of pharmacology, Marquette University School of Medicine, Milwaukee, has been appointed American collaborating editor of *Clínica y Laboratorio*, published in Zaragoza, Spain.

GENERAL

Radium Lost—A package containing 50 mg. of radium in the form of four standard monel metal needles, each measuring about 27 by 175 mm. in diameter, was mailed to Dr. Donald D. Stoner, Flatonia, Texas, by Dr. Harold Swanberg, Quincy, Ill. Thus far, Dr. Swanberg reports, it has not been received by Dr. Stoner and has apparently been lost or stolen. The package was dispatched by special delivery insured mail.

Change in Status of Licensure—The California State Board of Medical Examiners reports the following action taken at a meeting, Oct. 19, 1933:

Dr. George B. Dewees, Fresno, found guilty of habitual intemperance and placed on probation for five years, ordered to report at each San Francisco meeting and not to violate any laws.

Dr. Robert S. Friend, Long Beach, license revoked for narcotic violation.

The Florida State Board of Medical Examiners reports the following:

Dr. Vladimir K. Jindra, Miami, license revoked Nov. 13, 1933 on the basis of several criminal charges including a criminal operation in 1933, a felony in 1917, a narcotic violation in 1933 and a conviction of the crime and offense of culpable negligence, 1930.

Valley Meeting—The thirty-ninth annual session of the Sioux Valley Medical Association convened in Sioux City, Iowa, January 23-24, under the presidency of Dr. Sidney A. Slater, Worthington, Minn. Papers were presented by the following physicians:

Alfred W. Adson, Rochester, Diagnosis and Treatment of Spinal Cord Tumors.

Austin C. Davis, Rochester, The Myxedema Problem.

Charles M. McKenna, Chicago, Significance of Blood and Pus in the Urine.

Philip C. Jeans, Iowa City, Certain Aspects of the Feeding Problem.

Owen H. Wangersteen, Minneapolis, Acute Bowel Obstruction.

Robert O. Schrock, Omaha, Fractures of the Tibia and Fibula.

Solon Marc White, Minneapolis, Nonpainful Features of Coronary Occlusion.

Frederick H. Falls, Chicago, Premature Detachment of the Placenta.

Numerous clinics were also included in the program.

Golden Jubilee of Annals of Surgery—The fiftieth anniversary of the *Annals of Surgery* is commemorated with a special volume, containing an editorial tribute on Dr. Lewis Stephen Pilcher, Brooklyn, who has served continuously as editor. The *Annals of Surgery* is the outgrowth of the *Annals of the Anatomical and Surgical Society*, which was the transactions of the Brooklyn Anatomical and Surgical Society, established in 1878. The first volume bears the date 1878-1879, but in the following year it became the *Annals of Anatomy and Surgery*, a monthly periodical under Dr. Pilcher's editorship. This arrangement continued until 1884, when he went abroad for special study in surgery. After he returned, however, the publication was issued as the *Annals of Surgery*. Dr. Pilcher received his degree in medicine at the University of Michigan in 1866 and the degree of doctor of laws from the same institution in 1900. He was adjunct professor of anatomy at Long Island College from 1879 to 1883, and professor of surgery at New York Post-Graduate Medical School from 1885 to 1895. In 1892 he was president of the New York State Medical Society and of the Medical Society of the County of Kings in 1900. He was president of the American Surgical Association in 1918. He was a member of the Board of Medical Examiners of the State of New York from 1913 to 1928. He retired from the U. S. Navy in 1872, having served since 1867 as assistant surgeon.

Medical Bills in Congress—Change in Status H R 7527 has passed the Senate, making an additional appropriation for the continuation of the Civil Works program. As passed by the Senate, the bill provides, in part, that the United States Employees' Compensation Commission "is hereby authorized in its discretion to provide for the initial payments of compensation and the furnishing of immediate medical attention through the local authorities of the Civil Works Administration." *Bills Introduced* S 2476, introduced by Senator Capper, Kansas, proposes that for the purposes of promotion, longevity pay, and retirement there shall be credited to the officers of the Veterinary Corps, and former officers of the Veterinary Corps now on the retired list, all full time service rendered by them as veterinarians in the Quartermaster Department Cavalry or Field Artillery S 2571, introduced by Senator Johnson California proposes to authorize the Secretary of the Interior to arrange with the several states for the education medical attention, relief of distress, and social welfare of Indians S 2574, introduced by Senator Walsh Massachusetts, proposes that all officers of the Dental Corps of the Navy who entered the service prior to July 1, 1918, and who had not on that date attained such minimum age as to provide for their eligibility for appointment to the Dental Corps of the Navy, and whose active service has been continuous, shall for purposes of precedence, be credited with their total active commissioned service S 2602, introduced by Senator Lewis, Illinois, proposes to include the name of Gustaf E Lambert among those honored by "An Act to recognize the high public service rendered by Major Walter Reed and those associated with him in the discovery of the cause and means of transmission of yellow fever" S 2688, introduced by Senator Sheppard, Texas, proposes to validate payments heretofore made by disbursing officers of the Army for the medical and hospital treatment of members of the Reserve Officers' Training Corps and of the Citizens' Military Training Camps who contracted disease in line of duty while en route to or from and while at camps of instruction H R 7259, introduced by Representative Celler, New York, proposes to confer additional benefits on veterans Among other things the bill provides that any World War veteran employed in the active military or naval service between April 6 1917, and Nov 11 1918, not dishonorably discharged in need of hospitalization or domiciliary care and unable to defray the necessary expenses thereafter, may be furnished the necessary hospitalization or domiciliary care in any Veterans Administration facility, irrespective of whether the disability was due to service A statement by the veteran that he is unable to defray the expenses necessary for hospitalization or domiciliary care must be accepted by the Administrator of Veterans' Affairs as conclusive evidence of that fact H R 7262, introduced by Representative Gasque, South Carolina and H R 7335, introduced by Representative Gillette, Iowa, propose to grant pensions and increases of pensions to certain soldiers, sailors and nurses of the war with Spain the Philippine insurrection or the China relief expedition, and their widows and dependents H R 7313 introduced by Representative Mitchell, Tennessee proposes to authorize the erection of a veterans hospital in middle Tennessee H R 7350, introduced by Representative Ludlow, Indiana, proposes to grant pensions and increases in pensions to certain soldiers and sailors of the war with Spain the Philippine insurrection, or the China relief expedition, to certain maimed soldiers, to certain widows, minor children and helpless children of such soldiers and sailors H R 7802 introduced by Representative Black New York provides for the further development of vocational education in the several states and territories H R 7804, introduced by Representative Cochran, Missouri, proposes to authorize the Reconstruction Finance Corporation to make loans to any public or private hospital organized under the laws of any state

Deaths in Other Countries

Angel Brioso Vasconcelos, Mexico City professor of hygiene, Military School of Medicine, 1923-1933 clinical professor of venerology, National School of Medicine, 1925-1927, for many years chief of the department of disinfection in public health service, editor of *Gaceta Medica* 1919-1927, correspondent to THE JOURNAL, 1919-1925 member of many scientific societies and author recently aged 50—**Sir Donald Mac alister**, since 1904 president General Medical Council, chairman, British Pharmacopoeia Committee author, London, January 14, aged 79—**Sir William Bate Hardy**, biologist and refrigeration expert, aged 69, died in Cambridge, January 23 Sir William delivered the Flexner Lectures at Vanderbilt University School of Medicine, Nashville, Tenn, in 1931—**Dr Bernard Hollander**, founder and president of the Ethnological Society and past president of the Societe Inter-

nationale de Philologie, Sciences et Beaux-Arts, editor of the *Ethnological Journal*, and formerly clinical assistant to Professor Kraft-Ebing, Vienna, and author of numerous tracts on psychotherapy, aged 69, following an operation

Government Services

Dr Whitehead Named Director of Aeronautics

The appointment of Dr Roy E Whitehead, Indianapolis, as chief of the medical section of the aeronautics branch of the U S Department of Commerce, Washington, D C, succeeding Dr Eldridge S Adams, resigned, has been announced Dr Whitehead, who is 40 years old, graduated from the Indiana University School of Medicine in 1920 He is also a graduate of the army school of aviation medicine and is at present the Indiana governor of the National Aeronautics Association

Monthly Meetings of Naval Officers

Rear Admiral Perceval S Rossiter, surgeon general of the U S Navy, has initiated monthly meetings for the medical officers living in and near the District of Columbia At each meeting a subject of medicomilitary or scientific interest will be presented and a social hour will follow At the first meeting, October 2, the surgeon general discussed current activities of the department and at the second, November 6, Dr Victor G Heiser of the Rockefeller Foundation spoke on "Medical Observations During the Past Year in Many Lands" Dr Maurice C Pincoffs, professor of medicine University of Maryland, Baltimore spoke, January 8, on "Clinical Aspects of Various Types of Respiratory Difficulty"

Federal Expenditures for Emergency Medical Relief

The Federal Emergency Relief Administration expended \$3,291,970 for medical care throughout the country from July 1 to Nov 30, 1933, according to a report issued January 27 Expenditures by months were as follows July, \$921,137, August \$989,489, September, \$941,486, October, \$911,666 November, \$852,882 A table of amounts allocated to individual states for November shows that the largest amount went to Indiana, which received \$115,906 31 Illinois, \$84,797, Wisconsin \$63,062 38, Massachusetts \$47,219 61 and New Jersey \$43,004 71 No funds were expended by Idaho, Michigan, Oklahoma, Texas or Wyoming These figures do not include expenditures of the government for medical treatment for occupational injuries sustained by the 4,500,000 persons temporarily employed by the Civil Works Administration who come within the scope of the Federal Employees Compensation Act

Medical Center for U S Penal System

The opening of the U S Hospital for Defective Delinquents, Springfield, Mo, marks the completion of a program of prison improvement authorized by Congress in May 1930 The new hospital is considered an essential unit in the government's attempt to specialize the treatment of persons committed to its care It will be used only for prisoners over whom the federal government has assumed jurisdiction When the prisoner finishes his term he will be returned to the state of his domicile for further care and treatment Said to be the only one of its kind in the world, the institution will serve as a medical center for the entire federal penal system The first prisoners to be transferred will be a group of mental patients now cared for at St Elizabeth's Hospital, Washington D C, and later the sick and insane prisoners now inadequately housed in federal prison hospitals The institution will also care for prisoners who during the time of their detention, become afflicted with an incurable or chronic degenerative disease, or become so defective mentally or physically as to require special medical care and treatment not available in an existing federal institution The site, consisting of 445 acres donated by citizens of Springfield, was selected as the most suitable of about thirty sites offered Besides being located centrally with reference to all the widely scattered institutions in the federal system, the hospital has a favorable climate because of its location in the Ozarks region and its elevation Eight buildings have been erected thus far at a total cost of \$2,040,983 The center will accommodate 705 patients and the average bed cost per patient will be about \$2,900 Dr Lawrence Kolb of the U S Public Health Service will be in charge The hospital was formally dedicated September 22

Report of Surgeon General of Navy

For the third year in succession, motor vehicle accidents were responsible for more deaths and noneffectiveness among the personnel of the United States Navy than any other group of hazards, being responsible for 70 deaths and 1,149 admissions to the sick list, according to the report of the surgeon general for the calendar year 1932. In 1932 only 34 deaths, including two suicides, were caused by drowning, which until 1930 was the leading cause of death in the navy. Of 371 deaths in the service, a decrease from 391 in 1931, 186 were caused by disease, 113 by accidental injuries and 3 by poisoning. There were 15 homicides and 19 suicides. Three war casualties were reported from the Marine Corps expeditionary forces in Nicaragua. Among diseases the leading causes of death were diseases of the circulatory system 35, pneumonia, 26, tuberculosis, 22, abscess, 10, appendicitis, 9, and influenza, 6. One death occurred from septicemic plague on a ship at Kuikang, China, and one from smallpox in Shanghai. The hospital admission rate for 1932 was 554.06, as compared with 565.92 for 1931. Of 61,344 admissions, 30.81 per cent were for communicable diseases transmitted by oral and nasal discharges, 24.12 for venereal disease, and 10.84 for wounds and injuries. There were 18,902 admissions in the first class, of which 13,110 were classified as cases of acute catarrhal fever, a term used to include the common cold. In this type of infection there was a 25 per cent increase over 1931, but the entire group showed a lower incidence than for the previous year. Influenza accounted for 1,637 admissions, compared with 2,384 for 1931. A moderately severe epidemic occurred, however, in July 1932 in the forces afloat, which assumed such proportions that movement of ships, gunnery exercises and other fleet activities were affected. These so-called minor infections are of more importance from the standpoint of the health of the navy than diseases such as measles, scarlet fever and diphtheria, the report says. Mumps was less prevalent than for the preceding ten years, with 124 admissions, a rate of 112 per hundred thousand, the median rate for the preceding five years was 427. Scarlet fever was unusually low, with a rate of 33 per hundred thousand, as compared with 71 for 1931. The lowest admission rate since 1924 was reported for Vincent's angina, 543 per hundred thousand. Three cases of smallpox and three of acute anterior poliomyelitis were reported. Venereal disease was second in number of admissions with 14,794, a slight reduction from the previous year. Wounds and injuries were third with 6,588. The report noted 3,684 surgical operations. During the year 63,152 persons were cared for in naval hospitals with a total of 2,621,429 treatment days. Of the number treated, 37,504 were patients of the Veterans' Administration, 20,679 of the navy and 4,969 of supernumeraries. A total of 1,259 persons were invalided from the service during the year. In a report covering activities of the medical department for the fiscal year ended June 30, 1933 the surgeon general reports the closing of the Naval Hospital at Great Lakes, Ill. and the beginning of construction of a new hospital at Philadelphia in February 1933. The loss of the airship *Akron* April 4, 1933, resulted in the death of sixteen officers, one warrant officer and fifty-five enlisted men. At the close of the fiscal year the force consisted of 891 medical officers, 192 dental officers, 140 warrant officers, 466 nurses and 3,794 hospital corpsmen. Two hundred and nine medical officers were on duty with the Civilian Conservation Corps but will be gradually returned to duty. There were forty-nine qualified flight surgeons in the division of aviation medicine at the close of the fiscal year. There were 508 medical officers and 188 dental officers in the reserve corps. During the year eleven new officers were commissioned and twenty-four were separated from the service—eleven by retirement, eight by resignation and five by death. Research projects of the year concerned the use of the submarine lung, deep sea diving, chemical warfare, ventilation of ships and physiologic effects of sudden changes in speed and direction of airplane flight.

CORRECTION

Discussion by Dr. Gutierrez—In the abstract of discussion in *THE JOURNAL*, January 20, page 192, the word 'cystoscopy' is incorrectly used for the word 'cystostomy' in the discussion of Dr. Robert Gutierrez of New York. In the fourth line from the end of this discussion the part beginning with 'first removing the obstruction' should read as follows: 'first a cystostomy is performed to relieve the infection and back pressure, secondly a prostatectomy to remove the obstruction and thirdly, a diverticulectomy.'

The Voluntary Sterilization of Mental Defectives

In 1932 the minister of health received a deputation from the Association of Municipal Corporations, the County Councils Association and the Mental Hospitals Association, because of the growing burden on the community imposed by mental defectives. The result was that a sterilization committee was appointed to consider the prevention of the propagation of defectives. Among the members were Mr. Wilfred Trotter, sergeant surgeon to the king, eminent both as a surgeon and as a philosopher, Dr. A. F. Tredgold, an authority on mental deficiency, Prof. R. A. Fisher, and Dr. R. H. Crowley, senior medical officer of the board of education. They made careful inquiries into the causes of mental deficiency and mental disorder and heard the evidence of sixty witnesses among whom were representatives of the Royal Colleges of Physicians and Surgeons, biologists, geneticists, psychiatrists and social workers. Nearly all the witnesses agreed in principle as to the legalization of voluntary sterilization and the undesirability of permitting mental defectives and persons liable to recurrent attacks of insanity to become parents. The committee's report has just been published. It considers that a calculation previously made by another committee that the number of mental defectives in England and Wales was not less than 300,000 is not an overestimate. As far as the committee can see, the incidence of mental deficiency is increasing, though not at a rapid rate and there is no ground for the alarmist talk of wholesale racial deterioration. It finds that inheritance plays a large part in the causation, in not less than 80 per cent of the cases it is a contributory factor, although in many instances unfavorable environment is also a cause. The committee made an inquiry, which it considers of great importance. For the first time, instead of asking what kind of parents the defectives had, the investigators asked what the children of defectives were like. They found that of 1,800 children of mental defectives between 7 and 13 years of age, 40 per cent were subnormal mentally, and of 1,850 children over 13 years of age, 45 per cent were mentally subnormal. As one fourth of the children of the mentally defective parents under review had died and the percentages apply only to survivors, it is submitted that the figures indicate an urgent problem. In regard to what is comprehensively termed 'insanity' by the public, the committee considers that inheritance here also plays a large part in causation.

THE COMMITTEE'S RECOMMENDATION

The committee was impressed by two things: the dead weight of social inefficiency and individual misery entailed by such a large and increasing number of defectives and the injustice of refusing those who may have good grounds for believing that they may transmit mental defect and who are in every way unfitted for parenthood the only effective means of escaping from a burden they dread. Compulsory sterilization the committee rejects, as it could be justified only if it could be shown that some of the offspring of a particular person were bound to be mentally deficient. In the present state of scientific knowledge this cannot with certainty be predicted by examination of one partner of a union. Also compulsion would defeat itself, for if public opinion is favorable it would be unnecessary, if indifferent compulsion would tend to turn indifference into hostility and mental deficiency would be driven under ground. The committee therefore recommends that voluntary sterilization be made legal. Voluntary absti-

nence is not a remedy. It is idle to expect that the section of the community least capable of self control will restrain one of the strongest impulses of mankind. When the patient is not competent to give consent, that of the parents or guardians must be obtained. When the patient cannot bear the full cost of the operation, this will be paid by the authorities concerned. In all stages the procedure is to be treated as confidential. The patient, when married, must notify the spouse of the application. The committee points out that legislation in America has been effective only in those states in which sterilization is performed on a voluntary and not on a compulsory basis. The committee's recommendations are wider than its terms of reference—that sterilization should be legalized also for persons suffering from or liable to transmit a grave physical disability, such as blindness, deaf mutism, hemophilia and brachydactylia. "The case for legal sterilization," it says, "rests on the broad principle that no person, unless conscience bids, ought to be forced to choose between complete abstinence from sexual activities and risking bringing into the world children whose disabilities will be a burden to themselves and to society." In the case of a person who has suffered from mental disorder, the operation should not be performed until a competent psychiatrist has reported that in his opinion no injurious results will be likely to follow. In all cases in which the patient is capable of giving consent he should sign a declaration of willingness to be sterilized. Physicians in recommending sterilization should have protection similar to that accorded in the certification of lunacy. Two medical certificates are to be required for each operation, one from the family physician and one from a physician on a list approved by the minister of health. Doubtful cases are to be referred by the minister to a small advisory committee of physicians and geneticists.

As there may be considerable difficulty in determining the applications of persons who are suffering from or are believed to be the carriers of inherited diseases and disabilities, the committee advises the appointment of a small advisory committee of physicians and geneticists to which the ministry of health may refer doubtful cases. It is recommended that sterilization shall not be performed in any mental hospital or mental deficiency institution, so that the impression may be avoided that it is in any way connected with the institution.

Increase of Road Accidents

Every day in 1933, 19 persons were killed and 592 injured on the roads of Great Britain—an increase in the deaths of more than one per day over those of 1932. This alarming toll is shown in the official figures for 1933, just issued:

	1933	1932	Increase
Total road accidents in Great Britain	191 829	184 006	7 823
Total deaths	7 125	6 667	458
Injured persons	216 401	206 450	9 951
<i>London</i>			
Killed	1 409	1 266	143
Injured	56 967	52 447	4 520

The streets of the big cities and towns are the most dangerous, with London the worst.

This increase of accidents is disappointing, in view of the fact that the government has attempted to deal with the terrible road peril by legislation and that such devices as one-way traffic, marking of the roads, danger signals and automatic control of traffic by colored lights have been introduced. Concern has been expressed in many quarters. Sir A. K. Butterworth, chairman of the Pedestrians Association, is more convinced than ever that, until speed on the roads is reduced, improvement cannot be expected. The increase of accidents does not imply more dangerous driving, for it may be due to the greater number of automobiles. A census taken last summer by the Automobile Association showed an increase of a million vehicles over 1928.

Improvements in X-Ray Technic

At the congress of the British Institute of Radiology, Dr. A. Bouwers of Eindhoven delivered a lecture on "Modern X-Ray Developments" and showed one of the smallest x-ray machines in the world, an instrument weighing only 7 pounds and capable of taking perfect photographs in two seconds. He described the chief objects of modern developments as the obtaining of still better results and greater simplicity of method. The Geiger counter was a highly sensitive device for dose measurement but so far had been used exclusively for other radiation. Referring to the disintegration of atoms, he said that if the application of the neutrons in combating cancer proved successful it was still an open question whether the interesting method of Lawrence or the method of the high tension generator would constitute the best source.

Inferiority of Artificially Prepared Vitamins to Fresh Foods

Lecturing to the Edinburgh Women's Citizens' Association, Dr. Chalmers Watson said that the clinical value of vitamins prepared in the laboratory fell far short of expectations based on the claims made. The impression was gaining ground that by far the best way of administering vitamins was to give a sufficiency of good fresh foods.

Vaccination Against Diphtheria

It will be recalled that Mr. Ramon and Mr. Debre, by increasing the potency of antidiphtheritic anatoxin (toxoid), were able to reduce the number of injections and to confer, at the same time, a stronger and more durable immunity. Several hundred children have been vaccinated, in Belgium, France and Tunisia, by means of two injections (1 and 2 cc., respectively, with an interval of three weeks) of a diphtheritic anatoxin with a potency of twenty antigenic units. One month after the second injection, 99.5 per cent of the children had become immunized, as shown by a negative Schick test. The conferring of immunity by means of two injections of an anatoxin, with a potency of at least twenty units, does not render superfluous the precaution of giving a third injection, six months or a year or more, after the vaccination. By this precaution one reinforces the immunity of certain children in whom the amount of antitoxin received was scarcely sufficient immediately after the vaccination or in whom the immunity conferred has become reduced, and one strengthens in this manner the resistance of vaccinated subjects toward diphtheria. The immunity is further strengthened if, at the same time, an injection of antityphoid vaccine is given. This fact was discovered by Mr. Crouzon, but Mr. Ramon has fully confirmed that the two vaccinations (antidiphtheritic and antityphoid) given simultaneously, instead of inducing an antagonism, mutually strengthen each other in a remarkable manner. One secures in this manner a much stronger and more durable immunity.

Treatment for Operative Shock

Professor Pauchet recently recommended a treatment for accidents ascribable to operative shock, with which he states that he has secured excellent results. Blood transfusion aids only in the event of fall of arterial pressure or loss of blood cells through hemorrhage. Pauchet decided to use embryonic tissues, which are rich in trephones. Embryonic tissues of cows—which exert a cytogenic action on the cells of all tissues—had already been employed. Pauchet, finding that those trephones do not keep well, used the trephones of a chicken embryo, prepared as occasion requires. He selects embryos from eggs that have been incubated from nine to eleven days. He grinds them up

with physiologic solution of sodium chloride, filters the mixture, and then transfers it to ampules containing 100 cc each, without sterilization. It should be used within forty-eight hours by the buccal route or, which is still better, by rectal injection. Pauchet administers one ampule a day for the two days preceding the operation, in order to increase the resistance of the subject. In case of shock during the operation, he prescribes another ampule. Then, if signs of shock appear after the operation, he prescribes an ampule at the end of 36 and of twelve hours. The observations reported by Pauchet are extremely convincing. It was a question of patients who had undergone long operations for gastric or intestinal ulcers, with extensive resections of the digestive tract, who nevertheless, on the following day, were in good condition, with normal blood pressure and good color.

Sedentary Diseases

The recent session of the Société de pathologie comparée was devoted to a single topic, the disorders incident to a sedentary life. Dr. Bellin du Coteau, an ardent sport advocate, began his remarks with the statement that intensive physical culture belonged only to youth, and primarily to the period that precedes the completion of body growth. Later, its role is merely to preserve, by proper training, the results acquired. One should not expect, when taken up late in life, that it will modify the constitution. Mr. de Chaisemartin emphasized the need of medical supervision of all intensive sport activities. Professor Marcel Labbé discussed the effects of a sedentary life on organic equilibrium. The disorders are manifested by the development of a type of obesity which differs from that due to excessive diet. The locomotor apparatus—muscles, bones, joints—is deeply affected, which is manifested by muscular atrophy and the weakness of movements, stiffness of joints, and fragility of the bones. The respiratory functions are diminished and the thorax does not develop properly. The circulatory functions are retarded and the extremities are cold. Digestion is poor. Finally, the intellectual energy and the morale become impaired. Mr. Boigey, who described the situation with even greater preciseness, said that in some persons who have led a highly sedentary life for a long time and have abandoned all forms of physical exercise there develops an infiltration of the cellular tissues by the body fluids. One observes in them a sort of general inhibition of the movability of the smooth muscles, a condition resulting in tenacious algias in the areas of the infiltrated cellular tissue. In this process no trace of inflammation or infection can be discovered. There is never any rise of temperature. Such a condition is due solely to algias associated with cellular infiltration. Hereditary tuberculosis, chronic alcoholism and syphilis frequently predispose these subjects to cellular infiltration. But it is chiefly hereditary deficiency of elastic tissue that constitutes the predisposing cause. In many subjects so affected there are concomitant ptoses, hernias, gastric dilatation, varices and livid streaks on the thighs and breast.

The treatment may be summed up in two words: exercise and massage. Exercise increases metabolism and favors the fixation of oxygen in the tissues. It checks in this manner the production of acidity and prevents hydrophilia of the tissues from manifesting itself.

Deaths

Dr. Leopold Lévi, who has died at an early age, was the best known specialist in endocrinology in France. His book, *Ophothérapie endocrinienne*, was awarded a prize by the Académie of Sciences. Professor Achard had created for him a special consultation service in endocrinology in his department at the Hôtel Dieu.

Dr. Boureau, the chief anesthetist of Professor Gosset, has died under peculiar conditions. During sleep a dental bridge

became detached and entered the lung. In spite of three interventions to remove the foreign body, which roentgen examination revealed clearly, the patient succumbed to pulmonary gangrene.

The Health of the Youth of Germany

According to statements of Dr. Hans Hoske, consulting physician for the department of juvenile welfare connected with the public works administration, health conditions among the youth of Germany pursuing a gainful occupation are unfavorable. In general, about a third of the juveniles do not present a full capacity for work. The percentage of apprentices who are in need of treatment or prolonged relaxation is much higher in the large cities (43.3 per cent) than in the cities with a population under 20,000 (33.04 per cent). The cities of East Prussia, surrounded by a healthy rural population, present a much lower proportion of persons in need of treatment (22.2 per cent) than the average of the small cities (33.47 per cent). The damaging effects of city life, as regards air and light conditions, are especially marked in the girls. Dr. Hoske calls attention to the circulatory disturbances in juveniles and to the nervous conditions especially in girls. Only 38 per cent of the girl apprentices and 37.5 per cent of the boy apprentices take systematic bodily exercise. From this neglected class of persons come later those who constitute a heavy burden for the social insurance system. It will be necessary, with respect to the juveniles who have just finished their schooling, to introduce frequent vacations into the working period, and gradually, at the end of the apprenticeship, to accustom them to the working hours of adults. Furthermore, large numbers of young persons gainfully employed do not have an adequate legally regulated paid vacation. This problem is absolutely in need of federal regulation. It appears that, in the future, supervised vacations (that is to say, control with a view to enforcing proper rest and recreation) will have to be inaugurated.

The Law Pertaining to the Protection of Animals

In May 1933, through changes in the penal code, increased protection was given to animals (*THE JOURNAL*, Sept. 23, 1933, p. 1011), and now the federal law, which becomes effective, February 1, has been published. The law states that "Unnecessary tormenting or rude treatment of animals is prohibited," and that is explained in the next provision: "Any person who causes an animal long continued or repeated pain or suffering of a noteworthy degree is guilty of tormenting such animal. Tormenting of an animal is unnecessary if it serves no reasonable justified purpose. Any person who causes an animal considerable pain maltreats such animal. Maltreatment is rude when it results from a lack of feeling." Certain forms of tormenting are prohibited in detail: neglecting an animal that is being cared for so that it suffers from such neglect; noteworthy pain or marked damage using an animal unnecessarily for the performance of work that is evidently beyond its strength; and causes it noteworthy pain, this applies also to animal training, preparation of motion pictures, and the like, when associated with noteworthy pain or damage to health, the disposing of or acquiring of a domestic animal that is ill, weak, worn out or old and for which continued existence is a torment, for any other purpose than immediately to put it out of its misery by a painless process, the exposing of an animal to the elements, in order to get rid of it, the training of dogs by inducing them to chase living cats, foxes, or other animals, or testing them in such manner the clipping or cutting of the ears or tail of a dog more than 2 weeks old except under anesthesia, the shortening of the dock of a horse, except in

case of disease (and then only by a veterinarian under anesthesia), the carrying out of any painful intervention on an animal in an unsuitable manner and without anesthesia, as painful interventions may be mentioned in detail the castration of horses, bovines or swine (if more than 3 months old) or pubescent rams and he-goats. Anesthesia is not required in interventions on animals if the pain involved is but slight or if similar interventions are commonly performed on man without anesthesia or if, in the opinion of veterinarians, anesthesia is impracticable. The application of forced feeding to poultry is prohibited, likewise the detachment of legs of living frogs.

Regulations concerning experiments on living animals, as finally adopted, supersede the temporary provisions announced a few months ago (*THE JOURNAL*, Oct 28, 1933, p 1404). In principle, persons are prohibited from performing interventions on living animals or applying treatments to them if such interventions are associated with noteworthy pain or damage; this prohibition covers all painful and operative experiments including bloodless or other experiments. The term "experiment" comprises not only the first intervention or the first treatment but also the whole course of an experiment extending over a longer period of time. These special regulations are designed for the speedy elimination of unauthorized persons who have heretofore engaged in animal experimentation. The federal minister of the interior may extend to certain scientific institutes permission to perform animal experiments, if all requirements have been met. Any person however who undertakes such experiments without permission shall receive a prison sentence up to six months, in addition to the imposition of a fine. Only reliable persons who have completed a course in a university will be regarded as responsible directors of institutes. Experiments may be carried out only on the full responsibility of the scientific director or his specifically empowered representative, and only by properly trained persons or under their direction, and then only with the avoidance of all unnecessary infliction of pain. Experiments for research purposes may be undertaken only in case they promise a definite result not yet confirmed by science or serve to clarify previously unsolved problems. Experiments may be performed only under anesthesia (local or general) unless, in the opinion of the scientific director, the purpose of the experiment absolutely excludes anesthesia or in case, by the application of anesthesia, an animal would be worried more or its well being would be more impaired than by the intervention to be performed. In the exceptional cases in which a severe operative or bloodless painless experiment must be undertaken, no second experiment of the kind may be performed on the same animal. In extensive interventions or in the event of extreme pain, animals should be killed at once. Experiments on horses, dogs, cats or monkeys may be performed only when through experiments on other animals the objective cannot be attained. Animal experiments for instruction purposes are permitted only in the event that pictures, models, prepared specimens and films do not suffice. Reports should be made of animal experiments—which should include a clear statement of their purpose. Exceptions to these provisions lie in favor of experiments connected with the administration of justice, and vaccinations and blood withdrawals for diagnostic purposes or for the obtaining or testing of serums or vaccines in accordance with recognized or officially approved procedures. Here too, if conditions require it, animals should be painlessly killed.

Dr Giese, the administrator in the federal ministry of the interior, stated that, through the application of these strict officially controlled measures a guaranty would be furnished that experiments on living animals will no longer be regarded by a large portion of the population as cruel or immoral acts but rather as an important link in the chain of research methods. Accordingly, the daily press is expected to refrain from publish-

ing reports of experiments on living animals, and the medical press is urged to describe, if occasion arises, all animal experiments in such a manner that it is apparent that all possible consideration was shown the experimental animals.

The penalties have been greatly increased. Unnecessary tormenting or the cruel treatment of an animal renders a person liable to a prison sentence up to two years, in addition to a fine. It may be ordered also that the tormented animal shall be cared for elsewhere, up to three months, at the expense of the guilty party. If any individual wilfully or through carelessness shall neglect to restrain children or other persons under his (or her) supervision, and belonging to the same household, from acting in violation of this law, he shall be subject to punishment.

Another result of the new law is the official merger of the 679 societies for the protection of animals to form the *Reichstierschutzbund* the president of which is Dr Buttman, the director of the department of public instruction associated with the federal ministry of the interior.

The Hygienic Conditions of Sanatoriums

The economic situation of the convalescents' homes and sanatoriums of the carriers of the federal insurance system has become so unfavorable that an investigation and reorganization committee with participation of the *krankenassen* has been appointed to improve the sanitary conditions in these institutions. A general shifting of patients and a reassignment to be effected by a central committee are planned. Institutions that, from an economic and a medical point of view, have proved to be impracticable will either be closed or used for other purposes. In 1931 the homes of the *krankenassen* were occupied only up to 50 per cent of capacity and in 1932 only up to 30 per cent so that many *krankenassen* have had to raise their rates charged in these homes in order to pay operating expenses. The mistake that has caused the most trouble is that many *krankenassen* thought that they ought to have a convalescents' home or a sanatorium of their own (or sometimes more than one) so that, in many regions, more homes exist than there is need for, with the result that all in recent years, have been only partly occupied.

Treatment of Hydrocyanic Acid Poisoning

The experimental work of Dr Enrique Hug shows that an antidote for hydrocyanic acid poisoning is the association of sodium thiosulphate and sodium nitrite. Sodium nitrite injected intravenously changes some of the hemoglobin into methemoglobin. The methemoglobin, in turn, combines with hydrocyanic acid to form a less toxic cyanhemoglobin. Then sodium thiosulphate is injected. If used alone intravenously, sodium nitrite or sodium thiosulphate may save persons poisoned by hydrocyanic acid but if given together their efficacy increases. Amyl nitrite may be given by inhalation at first to get rapid action but its value is less than that of sodium nitrite intravenously. These studies have been made in a large number of rabbits poisoned by ingestion and in dogs poisoned by the subcutaneous and intravenous routes. Two human cases at Montevideo and at Rosario have been observed. In man it is advisable to give doses of from 0.1 to 0.2 Gm. of a 2 per cent solution of sodium nitrite, intravenously, alternating with injections of from 2 to 3 Gm. of a 20 per cent solution of sodium thiosulphate. The injection of sodium nitrite should never exceed 1 Gm. The life of one of the patients was saved after the injection of 1.5 Gm. of sodium nitrite but severe cyanosis appeared.

Study of Hydatidosis

Dr Juan Bacigalupo, associate professor of parasitology in the Faculty of Medicine of Buenos Aires, has reported to the Societies of Biology and Surgery some important work on echinococcosis. He observed that the scolices introduced either in the stomach or in the rectum of rabbits or guinea-pigs migrate through the intestinal mucosa and some reach the peritoneal cavity. A few days later numerous scolices are found in the lung, where they give the lung the appearance of having pneumonic or miliary foci. He believes that the probable route of the scolices is through the intestinal lacteals to the thoracic duct and then through the large veins to the lung. These experiments show that the presence of scolices in the intestine of mammals is as dangerous as the presence of ova of *Taenia*, as they lead to infestation of the organism, with the production of hydatid cysts. The partial rupture of hydatid cysts into the biliary system, allowing the passage of numerous scolices into the intestine, is a frequent occurrence. The scolices then can traverse the intestinal wall, causing the reinfestation of the patient and the production of new cysts. The rupture of hydatid cysts into the bronchi may also permit the ingestion of some scolices.

Congress of Medicine to Discuss Amebiasis

The fifth Congress of Medicine will take place in Rosario, September 2-9. The national government has given 100 000 pesos (\$25 000) for this purpose. The committee on organization, presided over by Dr Camilo Muniagurria, decided that amebiasis will be the official topic to be discussed. Drs O da Fonseca of Rio de Janeiro, Guido Izar of Milan, Dobell of London, Greenway Castele and Marotta of Buenos Aires and Mazza of Jujuy have been invited as official speakers. Drs Ludwig Aschoff of Freiburg and C de Moura Campos of São Paulo have also been invited to present papers on the subject. There will be discussions on anatomy, physiology and biochemistry, pathology, internal medicine, surgery and several specialties, and medical education.

Dysentery

Dr Sordelli has reported cases of bacillary dysentery in Las Varillas, Córdoba, Entre Ríos, Goya, Corrientes and the federal capital. The outbreaks have been local and with little mortality. Bacilli of the Flexner, Shiga, Sonne and some other types were isolated.

Exanthematous Typhus

Although there are epidemics of exanthematous typhus in Chile and Bolivia up to the present no cases have been observed in Argentina. Nevertheless some cases which do not seem to be of an endemic form have been reported from the provinces of Tinogasta, Catamarca.

Mottled Enamel

Dr Damon has collected data concerning the regions of Argentina in which 'mottled enamel' is observed. Muñoz has verified the increase of fluorides in the water supply of those regions.

Validity of Foreign Diplomas in Argentina

The College of Physicians and other similar local associations have asked that the requirements for revalidation of foreign diplomas be increased, demanding a minimum of five years stay in the country before the candidates are permitted to take the examination for practice. A law proposed by Senator Serrey has passed the senate, but it will not be passed, it seems by the chamber of deputies. This has caused great excitement among graduates of Argentine universities. This bill proposes that all Argentineans graduated in foreign countries may practice in Argentina without examination, their

diplomas would be considered valid by a simple declaration of the government. At present foreign physicians must take theoretical and practical examinations in clinical medicine, surgery and obstetrics in the faculties of medicine. Even this simple examination would be suppressed by the proposed law. The universities have protested, as they have the exclusive right to issue diplomas that permit professional practice in Argentina.

Lectures by Foreign Guests

Lectures have been recently given in Argentina by Professor Haen of Berlin on hygiene, Prof Faure Fremiet of the College of France, in Paris, on physicochemistry of the cell, and Prof Ludwig Fraenkel of Breslau on pathology and clinical pathology in women. During the year, Argentina will be visited by Filippo Bottazzi of Naples, L Binet of Paris, A Chatton of Montpellier and Ludwig Aschoff of Freiburg. Drs García Lagos, García Rossello, García Otero and Velasco Lombardini, all of Montevideo, have recently given lectures in Argentina on gastric ulcer, pulmonary radiology, photosensitivity, bronchial obstruction and electrocardiography, respectively.

RIO DE JANEIRO

Nov 20, 1933

Lecture on Yellow Fever

Dr Fred L. Soper gave a lecture before the National Academy of Medicine on yellow fever. He demonstrated that the endemic index does not always correspond with the culex index, which includes probably *Culex mansoni*, *Aedes aegypti* and *Psorophora*. He reported on studies made in the valley of Chanaan at Espirito Santo, where he had the opportunity of verifying the foregoing facts. The previous existence of yellow fever there was confirmed by immunologic studies on the blood of cured persons and by pathognomonic lesions of the liver found in persons who died.

The author pointed to the necessity of organizing, in suspected localities, a service of systematic necropsies of all persons who die in less than ten days of a febrile disease. This service has already been established by a law of the provisional government, and a laboratory of the Rockefeller Foundation in Bahia has made 29,000 postmortem verifications. Dr Soper reviewed the status of the yellow fever problem, which is not only Brazilian or continental but international, especially in relation to the west coast of Africa and to Central and South America. Dr Soper stated that new measures must be taken to eradicate yellow fever from the American continent. He praised the yellow fever services rendered by the department of public health and the spirit of cooperation of Brazilian sanitarians who have so nobly helped the Rockefeller Foundation. He recommended (1) the organization of an antilarval service in all cities, towns and villages suspected of being infected, (2) the creation of the postmortem service, (3) organization of the campaign against mosquitoes by a classification as complete as possible of the species found and verification of the possibility of transmission of the disease through them, (4) the organization of a service of rural sanitation, and (5) sanitary and economic measures to attain the proposed objects.

Opening of Surgical Tuberculosis Service

A few days ago the new surgical tuberculosis service of the General Polyclinic of Rio, directed by Prof A. MacDowell, was inaugurated. Numerous persons participated in the celebration. The new surgical section consists of a spacious and well equipped operating room, a modern sterilizing room, wards and an emergency kitchen. The new organization is an innovation here. It is the first surgical organization devoted especially to the treatment of pulmonary and bone tuberculosis installed in the country.

Treatment of Detachment of the Retina

Mr H Coppez, addressing the Royal Academy of Medicine, recalled that the new treatment for detachment of the retina has awakened great interest, as this disorder was formerly regarded as incurable. He surveyed the factors involved in this serious problem, which is approaching a satisfactory solution.

Gonin, about 1923, in attempting to remedy a laceration of the retina with the thermocautery, produced adhesions that attached the retina to the outermost coat of the eye. He then brought about adhesive chorioretinitis, by the Sourdille method, but confined it to the laceration and to the neighboring tissues. It will be recalled that Sourdille produces adhesive chorioretinitis by injecting under the conjunctiva a solution of mercuric cyanide and puncturing the outermost coat of the eye in several places.

Both of these operations, though they give satisfactory results, present serious inconveniences. The method of Guist and Lindner of Vienna, who inject a small drop of a 3 per cent solution of potassium hydroxide between the choroid and the sclera, and the more recent methods of using diathermy, led Leon Coppez to propose a new operative technic, which has given such results that the speaker did not hesitate to advocate giving it a trial. The technic consists of extraocular applications with the aid of a special electrode (pyrometric electrode), which enables the operator to measure exactly the dose of diathermocoagulation.

After determining the extent of the detachment and noting the retinal laceration, one prepares a diagram of the lesions. After three or four days' rest to bring about a temporary reapplication of the retina to the choroid, the sclera is denuded over the whole area corresponding to the detachment. The laceration is encircled by contiguous diathermic applications to form a continuous barrage of choroiditis. Diathermic applications are then made in parallel rows both vertically and horizontally throughout the denuded scleral area. Thus the laceration is remedied and the retina becomes attached throughout the whole detached area. In order to assure permanent contact of the retina and the choroid, it is necessary to evacuate the subretinal fluid, at the time of the operation and after the operation, by "trepaning" two or more of the lowest diathermic foci and incising crosswise the layer of scleral tissue that has been left.

Intestinal Tuberculosis

In the *Revue belge de la tuberculose*, Warmoes discusses secondary intestinal tuberculosis, which occurs in a considerable number of cases of arrested pulmonary tuberculosis. The intestinal lesions continue their evolution, whereas the pulmonary lesions are arrested. Intestinal tuberculosis takes three forms: ulcerous, fibrous (or hypertrophic), and ulcerofibrous (a mixed type).

Of 260 cases of pulmonary tuberculosis examined at Sysele, near Bruges, intestinal tuberculosis was found in seventy-two, or 27.6 per cent, of forty-three cases with beginning pulmonary lesions, in one, of fifty-seven cases with slightly evolutionary unilateral lesions, in two, of 108 cases of extensive evolutionary lesions, in thirty. In itself, intestinal tuberculosis does not always present an immediate grave prognosis. Some types develop slowly but produce a deterioration of the patient's general health.

Warmoes proposed forms of treatment: vitamins, roentgenotherapy, heliotherapy, surgery. He emphasized that, by means of radiology, it is possible to detect intestinal lesions and that consequently a radiologic examination is advisable in all cases

of pulmonary tuberculosis in which the general condition of the patient is worse than the condition of the lungs would lead one to expect.

Results Secured with Anatoxin

Numerous trials have been made in Belgium with antidiphtheritic vaccination by means of the specific anatoxin of Ramon, Timbal and Nelis, and particularly with immunization in two stages with diphtheritic anatoxin naturally rich in antigenic units (from 20 to 30 units). From the systematic application of vaccination with anatoxin, such as has been carried on for several years, and from the total number of observations made in 14,000 children vaccinated, these authors conclude that

Antidiphtheritic vaccination with anatoxin has been found virtually harmless. The anatoxin if properly prepared and controlled is incapable of provoking a specific intoxication of the slightest nature. The reactions that one may observe in certain persons are associated particularly with the amount of anatoxin in the form of specific antigenic substance, they are always transient and never dangerous. The vaccination never has any bad influence on the later development of the vaccinated child.

The injection of anatoxin is not followed by a negative phase, it does not make the vaccinated subjects more sensitive to diphtheritic infection or to other diseases.

If it possesses a sufficient number of flocculation units and is injected according to the prescribed technic, in the doses and in the intervals of time recommended, anatoxin produces immunity in a high percentage of vaccinated subjects.

The immunity conferred by the anatoxin is of long duration. The percentage of subjects immunized does not diminish during the years following the vaccination.

When applied in the form of two injections (from 1 to 2 cc., with an interval of three weeks, the anatoxin having a potency of at least 20 antigenic units), the vaccination is capable of developing an immunity that gives a negative Schick reaction in from 99 to 100 per cent of the vaccinated subjects. Thus, the reduction of the injections of anatoxin from three to two, and the immunity conferred on practically all the subjects vaccinated constitute a twofold improvement.

The numerous examples here given, which are drawn from an extensive application, prove that vaccination with anatoxin, undertaken systematically and properly, diminishes considerably the morbidity of diphtheria. It checks the progress of endemic and epidemic diphtheria. It constitutes, therefore, the preferred method for the individual and collective prophylaxis of diphtheria.

Marriages

CHARLES H. HALLIDAY, Baltimore, to Miss Frances Allen Steger of University Va., at Gettysburg, Pa., Dec 1, 1933.

GEORGE EDWARD URBAN, Baltimore, to Miss Ellen Josephine Stafford of Catonsville, Md., at Media, Pa., Sept 23, 1933.

FRANCIS WILCOX GLUCK, Baltimore, to Miss Jean Harvey Anderson of Port Deposit, Md., February 2.

MARTIN F. STEIN, New York, to Miss Cynthia Ruth Van Atten of East Orange, N. J., January 20.

JAMES GRADY FAULK, Pembroke, N. C., to Miss Sallie Jane Williams, at Wingate, Dec 27, 1933.

HYMAN MORRIS HUREVITZ, Iowa City, to Miss Edith Robinson of New York, Nov 12, 1933.

BYRON EUGENE BOYER to Miss Margaret Hall Richardson, both of Cincinnati, Nov 4, 1933.

WILLIAM WARREN SOUTHWICK, Marshalltown, Iowa, to Miss Vera Clark, Nov 17, 1933.

CHARLIE NEWTON WADDEN to Miss Eugenia Coleman, both of Macon, Ga., Dec 30, 1933.

SHELDON WILSON REAGAN to Miss Maryan Bryan, both of Elgin, Ill., January 20.

Deaths

Arthur David Dunn ☉ Omaha, Rush Medical College, Chicago, 1902, member of the House of Delegates of the American Medical Association, 1922-1929, professor and chairman, department of clinical research, University of Nebraska College of Medicine, formerly professor of medicine and clinical medicine and vice dean, Creighton University College of Medicine, member of the Association of American Physicians and fellow of the American College of Physicians, past president of the Missouri Valley Medical Society and president-elect of the Omaha Mid-West Clinical Society, on the staff of the Clarkson Hospital formerly on the staff of the Creighton Memorial, St Joseph's Hospital, at one time coroner's physician in Omaha, member of the council on medical education and as such member was active in making the survey of Nebraska hospitals, aged 60, died, January 8, of heart disease

George Edwin McKean ☉ Detroit, University of Michigan Medical School, Ann Arbor, 1894, professor of medicine, Detroit College of Medicine and Surgery, fellow of the American College of Physicians, past president of the Wayne County Medical Society, served during the World War, on the staffs of the Harper Hospital Woman's Hospital, St Joseph's Mercy Hospital, Evangelical Hospital and the Highland Park (Mich) Hospital, aged 65, died, February 4, of pneumococcal meningitis, acute otitis media and mastoiditis

Frederic William Sears, Burlington, Vt., University of Vermont College of Medicine, Burlington, 1888, member and past president of the Vermont State Medical Society, professor of neurology at his alma mater member of the New England Society of Psychiatry, president of the Burlington Health Commission, 1914-1917 neurologist to the Mary Fletcher, Fanny Allen and Bishop de Goesbriand hospitals, formerly superintendent of the Lakeview Sanatorium, aged 74, died, January 2

Robert Young Sullivan ☉ Washington, D C, Georgetown University School of Medicine, Washington, 1905, formerly associate professor of obstetrics and professor of gynecology at his alma mater fellow of the American College of Surgeons, on the staffs of the Georgetown University and Providence hospitals, Columbia Hospital for Women, and the U S Veterans Hospital, Diagnostic Center, aged 52, died, January 16, at Saranac Lake, N Y

Royal Tharp ☉ East St Louis, Ill., St Louis College of Physicians and Surgeons, 1906, past president of St Clair County Medical Society, member of the American Urological Association, on the staff of St Mary's Hospital, served during the World War, aged 49, was killed, Dec 21, 1933, in an automobile accident

Edward Mahlon Palmer ☉ Wichita Kan., University Medical College of Kansas City, 1904, member of the American Academy of Ophthalmology and Oto-Laryngology, fellow of the American College of Surgeons, on the staff of the Wesley Hospital, aged 59, died, Dec 31, of angina pectoris

Otto O Svebakken ☉ Decorah, Iowa, American College of Medicine and Surgery, Chicago, 1906, past president of the Winneshiek County Medical Society, on the staff of the Decorah Hospital, aged 58, was killed, January 12, in an automobile accident near Chiefland, Fla

Michael Shelly Picard ☉ Shreveport, La., Tulane University of Louisiana Medical Department, New Orleans, 1903, past president of the Caddo Parish Medical Society, on the staff of the Shreveport Charity Hospital, aged 54, died, Dec 31, 1933, of heart disease

Logan Lightfoot Thomas, Dawson, Ga., Georgia College of Eclectic Medicine and Surgery, Atlanta, 1897, member of the Medical Association of Georgia, veteran of the Spanish-American War, aged 68, died, Dec 11, 1933, of chronic nephritis

George Hempstead Kennett ☉ Kellogg, Idaho, Rush Medical College Chicago 1902 president of the Shoshone County Medical Society formerly physician and owner of the Wardner Hospital, aged 56, died, Dec 1 1933 of heart disease.

Harry English Shaw, Long Branch, N J., Bellevue Hospital Medical College, New York, 1898, fellow of the American College of Surgeons consulting surgeon to the Monmouth Memorial Hospital, aged 61 died, January 17 of pneumonia

Walter Winfield Widener, Mountain City, Tenn., Tennessee Medical College Knoxville 1900 member of the Tennessee

State Medical Association, served during the World War, aged 62, died, Dec 23, 1933, of cerebral hemorrhage

Arthur Jewett Lougee, Fryeburg, Maine, Columbia University College of Physicians and Surgeons, New York, 1896, member of the Maine Medical Association, aged 63, died, Dec 21, 1933, in Malden, Mass., of bronchopneumonia

Moses George Kotler, Malden, Mass., Tufts College Medical School, Boston, 1920, member of the Massachusetts Medical Society, aged 38, on the staff of the Malden Hospital, where he died, January 7, of pneumococcus meningitis

Joseph Hubert Ambrose Matte ☉ North Adams, Mass., Laval University Faculty of Medicine, Quebec, 1876, member of the school board, on the staff of the North Adams Hospital, aged 85, died, Dec 9, 1933, of pneumonia

John Christopher Smith ☉ Stacyville, Iowa, St Louis University School of Medicine, 1915, secretary of the Mitchell County Medical Society, formerly mayor of Stacyville, aged 45, died suddenly, Dec 29, 1933, of heart disease

Cecil W Brown, Clinton, Iowa, Western University Faculty of Medicine, London, Ont., Canada, 1906, member of the Associated Anesthetists of the United States and Canada, aged 57, died, January 8, of coronary thrombosis

Thomas Stamps, Lumber Bridge, N C., University of Louisville (Ky) School of Medicine, 1888, member of the Medical Society of the State of North Carolina, aged 85, died, January 24, in Norfolk, Va., of pneumonia

Delbert Warren McCrary, Lake City, Iowa, State University of Iowa College of Medicine, Iowa City, 1893, formerly connected with a hospital bearing his name, aged 65, died, January 8, in Pharr, Texas, of heart disease

George Henry Carveth, Toronto, Ont., Canada, Victoria University Medical Department, Coburg, 1884, member of the Associated Anesthetists of the United States and Canada, aged 75, died, January 27, of heart disease

Bryant M Tower, Conneaut, Ohio, Western Reserve University Medical Department, Cleveland, 1883, member of the Ohio State Medical Association, aged 75, died, January 9, in St Petersburg, Fla., of heart disease

Alexander Ambrose MacDonald, Boston, Georgetown University School of Medicine, 1895, member of the Massachusetts Medical Society, aged 69, died January 7, in St Martha's Hospital, Antigonish, N S., Canada

Bartlett Uttimus Sims, Bryan, Texas, Tulane University of Louisiana Medical Department, New Orleans, 1901, served during the World War, aged 55, died, January 6, of injuries received in an automobile accident

Andreas A Wipf ☉ Freeman, S D., Rush Medical College, Chicago, 1894, formerly member of the state legislature, aged 65, died, Dec 21, 1933, in the Sioux Valley Hospital, Sioux Falls, of lobar pneumonia

Horace Bradford Denman, Springfield, Vt., Hahnemann Medical College and Hospital of Philadelphia 1894, member of the Vermont State Medical Society, aged 64, died, Nov 26, 1933 in Peru, of heart disease.

John William Bosman, Kalamazoo, Mich., University of Michigan Medical School, Ann Arbor, 1885, member of the Michigan State Medical Society, aged 72, died, January 16, of cerebral hemorrhage

Emmett Johnson, Kinta, Okla., University of Tennessee Medical Department, Nashville, 1900, member of the Oklahoma State Medical Association, aged 67, died, January 1, of cerebral hemorrhage

David Bigger Best ☉ Wheeling, W Va., Rush Medical College, Chicago 1889, on the staff of the Ohio Valley General Hospital, aged 71, died, January 11, in Bridgeport, Ohio, of myocarditis

Isaac Reber Wolfe, Espy, Pa., Jefferson Medical College of Philadelphia, 1895, member of the Medical Society of the State of Pennsylvania, aged 69, died recently, of cerebral hemorrhage

William J Greene, Ringgold Ga., Chattanooga (Tenn) Medical College, 1896, member of the Medical Association of Georgia, aged 63, died, January 8, of nephritis and renal calculi

James Benton Messer, Bluestone, Ky., American Eclectic Medical College, Cincinnati, 1894, member of the Kentucky State Medical Association, aged 73, died, January 13, of heart disease

Ernest Leland Peet, Scranton Pa., Hahnemann Medical College and Hospital of Philadelphia 1896, aged 65, died, January 24, of injuries received when struck by an automobile

Albert Augustus Redelin ♂ Greeland, Pa., Jefferson Medical College of Philadelphia, 1893, served during the World War, aged 64, died, Dec 26, 1933, of cerebral hemorrhage

Oliver Wilson Spicer, Colorado Springs, Colo., Chicago Medical College 1873, member of the Colorado State Medical Society aged 85, died January 3, of cerebral hemorrhage

John Dike, Melrose, Mass., Boston University School of Medicine, 1888 formerly member of the school committee, aged 78, died, January 2, of carcinoma of the liver

Prince Albert Hobbs, Edgerton Kan., Louisville (Ky.) Medical College, 1890 aged 64, died Dec 7, 1933, in St Margaret's Hospital, Kansas City of heart disease

John W Cannon, Boise, Idaho College of Physicians and Surgeons, Keokuk Iowa 1873 aged 84 died Nov 26, 1933 in St Luke's Hospital, of cerebral hemorrhage

Friend Cook Suter ♂ La Crosse Wis State University of Iowa College of Medicine, Iowa City 1885 aged 76, died January 14, in New Orleans, of heart disease

Allen Cone ♂ Syracuse N Y Detroit College of Medicine, 1890 aged 69, on the staff of the General Hospital where he died January 8 of heart disease

Walter Thompson Bobo, Battle Creek, Mich., Marion-Sims College of Medicine, St Louis, 1899, aged 57, died January 17, of a self-inflicted bullet wound

Richard Emory Yellott, Benson, Ariz., Medical College of the State of South Carolina Charleston, 1906, aged 58 died, Nov 28, 1933, of heart disease

Henry Daniel Cunyers, Rome, Ga., Louisville (Ky.) Medical College, 1872, Confederate veteran, aged 85 died Dec 31, 1933, of chronic nephritis

Edward Otto Bang ♂ South Canaan, Pa Temple University School of Medicine, Philadelphia, 1906, aged 59 died, January 10, of coronary thrombosis

Le Roi Scott Syphers, Cornish Maine Medical School of Maine, Portland, 1904, aged 59 died, January 16, in a hospital at Portland of pneumonia

Ernest Levesque, Sudbury, Ont., Canada School of Medicine and Surgery of Montreal, Que., 1923 aged 35, died Oct 27, 1933, of cerebral hemorrhage

Nemours Caire, Westwego, La., Tulane University of Louisiana Medical Department, New Orleans 1895, aged 52 died, January 8 of heart disease

Christian Henry Brown, Philadelphia, University of Pennsylvania School of Medicine, Philadelphia, 1878, aged 76, died Dec 11, 1933, of heart disease

Amphas Milton Countryman, Cincinnati, Pulte Medical College, Cincinnati, 1881, aged 79, died, January 15, of diabetes mellitus and myocarditis

Fred Charles Dana, Fond du Lac Wis Chicago College of Medicine and Surgery, 1915, aged 47, died January 16 of acute dilatation of the heart

Burgess E Scruggs, Huntsville, Ala Meharry Medical College, Nashville, Tenn, 1879, aged 76, died, January 21, of myocarditis and influenza

John C Mitchell, Waldo Kan., Ensworth Medical College, St Joseph, 1897, also a druggist, aged 59 died, Dec 30, 1933 of heart disease

Benjamin Franklin Cox, Palmersville, N C College of Physicians and Surgeons, Baltimore, 1886, aged 83, died, January 4, of heart disease

James I Pollum, Du Bois, Pa Western Pennsylvania Medical College Pittsburgh, 1906, aged 57, died, Dec 30, 1933, of angina pectoris

Jay Lucullus McLaren ♂ Bell Calif Long Island College Hospital, Brooklyn, 1888, aged 72, died, January 23, of heart disease

Kossuth Tinker, Columbus, Ohio Medical College of Ohio Cincinnati, 1877, aged 78, was found dead, Dec 13, 1933, of heart disease

James C Banfield, Huntington, W Va., Eclectic Medical Institute, Cincinnati, 1885, aged 74, died January 12, of nephritis

H Eugene Delavergne, Kankakee, Ill Keokuk (Iowa) Medical College, 1896 aged 72, died, Dec 26 1933, of coronary disease

A MICRO-DYNAMICS PRACTITIONER

C Roland PerDue Makes Another Bid for Fame

Readers of this department of THE JOURNAL will doubtless remember the extended article that was published in the issue of January 6 on "Micro-Dynamics" It dealt with the evolution of a device known as the 'Micro-Dynameter' invented by Mr F C Ellis, who is not a physician but who has described himself as a consulting engineer The article also discussed not only the background on which the device is projected, but the claims made for it

**Nothing Is Hidden
from the
Micro-Dynameter**

This instrument makes a complete analysis of your health before your very eyes

It shows you the condition of your blood, nerves, muscles, glands and the different organs of the body

Locates disease — acute, chronic or hereditary—in any part of the body

Tells what drug or treatment will benefit you

Seeing Is Believing

The findings of this wonderful instrument are seen by every one alike. They are dynamic, scientific and accurate and can not be influenced by opinion or belief

Photographic reproduction (reduced) of a PerDue advertisement in an Indianapolis newspaper. Diagnosis reduced to the simplicity of a nickel in the slot gum vending machine

Following the appearance of the article, Mr Ellis issued *Special Laboratory Bulletin No 17*, in which, among other things, he says

The American Medical Association fully understood the experimental nature of Mr Ellis' early activities and evidently endorsed his scientific qualifications as late as 1928 when they sold him exhibit space at their National Convention at Minneapolis and carried his advertising for months in THE JOURNAL of the American Medical Association and in all of the State Medical Journals. Although advertising returns were unsatisfactory from those media, nothing personal whatever was contemplated by us in electing to make a dignified presentation of the Micro-Dynameter to the medical profession before the Inter State Post-graduate Medical Assembly and in *Clinical Medicine and Surgery*

There seem to be two obvious implications in this paragraph. First, that the American Medical Association in its official organ had carried advertisements of some of the preposterous devices exploited by the Electronic Research Laboratories or the Ellis Research Laboratories; second, that the recent article by the Bureau of Investigation on Micro-Dynamics was prompted by pique because Ellis did not advertise in THE JOURNAL. The answers to these implications are, first, that THE JOURNAL never advertised any of the fantastic devices dealt with in the Micro-Dynamics article and second, that Mr Ellis couldn't get into the advertising pages of THE JOURNAL at any price

It is a fact that a carbon arc lamp put out by the Ellis Manufacturing Company was advertised in a few issues of THE

JOURNAL between March 24 and June 30, 1928 This was during the period that the Council on Physical Therapy had the lamp under investigation When the Council completed its investigation of this lamp, however, it declared the device "unacceptable and "the policy of the company" which put it out "detrimental to public welfare" After Mr Ellis had received the Council's unfavorable report, he first wrote canceling his contract—which was unnecessary—and then asked to withdraw his cancellation and be permitted to continue to advertise He was told that his advertising was not acceptable to the pages of THE JOURNAL!

But the present article is not concerned with Micro-Dynamics or with Mr Ellis, but rather with a practitioner of Micro Dynamics and his professional methods The matter was brought to the attention of the Bureau of Investigation by the Better Business Bureau, Inc, of Indianapolis which, after receiving the tear-sheets of the Bureau of Investigation's article on Micro-Dynamics, wrote as follows

"In a recent tear-sheet we noticed an article on Micro-Dynamics We are enclosing an advertisement which appeared in a local newspaper and was inserted by C R PerDue, M D, a doctor with whom you are no doubt familiar, for your opinion"

It should be said in explanation that each week the Bureau of Investigation sends to every Better Business Bureau in the country, including the national organization, tear-sheets from THE JOURNAL containing articles prepared in the Bureau of Investigation and dealing with persons, products or methods of dubious scientific standing The advertisement that the Indianapolis Better Business Bureau sent with the letter just quoted is reproduced in miniature with this article

C Roland PerDue, according to his stationery, is a "Dermatologist, Plasto Cosmetic Surgeon" who has an office in the State Life Building in Indianapolis, Ind His stationery also carries the statements X-ray Therapy, Quartz Light Therapy, Electro Therapy, Skin Lesions, Facial Blemishes, Facial Surgery"

About the middle of December Dr PerDue wrote to the Bureau of Investigation of the American Medical Association as follows 'Please give me information regarding the Ellis Micro Dynamometer as advertised in *Clinical Medicine and Surgery*' As an article on Micro-Dynamics was in preparation and as the Bureau of Investigation had long had Dr PerDue's name in its files it was assumed, justly or unjustly, that the inquiry was not written in good faith, and it remained unanswered until the article on the Micro-Dynamometer was published, at which time Dr PerDue was sent pages from THE JOURNAL containing the article

The files of the American Medical Association have long contained material on Dr C Roland PerDue including several clippings from Indianapolis newspapers in which his name appears According to the records he was born in 1874 and holds a diploma issued by the Central College of Physicians and Surgeons Indianapolis, in 1897 He has an Indiana license granted in 1903

In THE JOURNAL for Nov 29, 1924 under "Indiana News," it was reported that a jury in the Superior Court of Indianapolis awarded one William A Trainor \$2,250 damages against Dr C Roland PerDue who was reported to have operated on Trainor's face Trainor had alleged that PerDue ruined his appearance and health by injecting paraffin

In 1928 a woman living in Indianapolis wrote to the American Medical Association stating that she had read an article in a lay magazine suggesting that persons who were considering taking X-ray treatment for the removal of superfluous hair write to the Association before undergoing such treatment The woman then went on to state

I went to Dr C Roland PerDue Plasto Cosmetic Surgeon 411 State Life Building this city expecting to take the Tricho treatments which he has been giving about ten years

Readers of this department of THE JOURNAL may remember that an article was published in the issue of Jan 19 1929 detailing the viciousness of the Tricho System of depilation

This article was later reprinted in extended form detailing a large number of additional cases of X-ray burns following the use of this method

In 1931 the state medical authorities of California reported that Orin Joslin, the quack who dabbled in such fakeries as "Intermittent Chromatic Radiant Ray" the 'Bio-Dynamo-Chromatic' charlatanism and various other fads, was in California using a marvelous machine that he called the "Ethereic Animator" This device was said to be the reincarnation of the Bio-Tactos" which he used when he was in the east, before he was arrested by the authorities of New York and run out of that state Joslin was arrested in California, and in an attempt to emphasize his respectability, it was reported that he showed the authorities a letter from C Roland PerDue, M D, 411 State Life Building, Indianapolis, endorsing Joslin and his methods

In August, 1931, the Department of Public Health of the State of Illinois reported to the Bureau of Investigation that C Roland PerDue of Indianapolis was using the Hoxsey "cancer cure" That PerDue dabbled in this form of quackery is evident from advertisements that appeared a year later (in 1932) in a Wheeling, W Va, paper at the time that Hoxsey was working his quackery at Wheeling In this advertisement it was stated that a group of Wheeling citizens took an automobile trip west with Hoxsey to visit what they called the Hoxsey Clinics located in various cities One of the stops, according to the story, was in Indianapolis To quote

'On the way back we stopped at Indianapolis and interviewed Dr C Roland PerDue who maintains a clinic for Mr Hoxsey and himself'

In 1932 a piece of advertising was put out by a concern known as the Institute of Aetheronic Therapy which had one 'Dorr Eldred Wood, LL B, D O, O D, M-T D, D C, M D' for its 'director' The 'Aetheronics' method of treatment was said to be by radio—a sort of mechanized Christian Science absent-treatment In the booklet already referred to there were quoted what purported to be the opinions of a number of physicians on the virtues of Aetheronics One of these was credited to C Roland PerDue, M D, 411 State Life Building, Indianapolis

In 1933 PerDue, according to information received, had joined the ranks of those faddists who would have one believe that the use of aluminum cooking utensils produces dire results, from what is loosely described as stomach trouble" to cancer

In 1934, as the advertisement which we reproduce shows, Dr PerDue is exploiting the mysteries of Micro-Dynamics This seems to be a fitting consummation to the doctor's previous professional record

Correspondence

BIOCHEMORPHIC VERSUS CHEMO- PHARMACODYNAMIC

To the Editor —I have read with great interest the admirable address of Prof C D Leake on "The Role of Pharmacology in the Development of Ideal Anesthesia," published in THE JOURNAL, January 6 To me one of the most interesting parts of this paper is the first footnote, in which Dr Leake suggests the coming of a new word "biochemorphic" Devotees of the basic medical sciences, and particularly of pharmacology, should be grateful to Dr Leake for emphasizing one of the most important aspects of pharmacology—in my opinion, the most important aspect of that science—namely, the relationship between the chemical constitution or structure (including physical properties) and the physiologic or biologic effects of drugs This is a field in which I have been active in a modest way, and in connection with my work I have often felt the greatest need of an adequate term, substantive and adjective which would succinctly convey this idea of relationship between chemical structure and pharmacologic action The word 'bioche-

morphic," proposed by my friend Professor Leake, does not seem to me satisfactory. To begin with, the first component of the word "biochemorphic" is somewhat redundant, as the term "chemical" without the prefix "bio" would more accurately express the idea intended. There is no longer any distinction made between chemical compounds, inorganic, organic or biochemical. More unsatisfactory is the second component of the word "biochemorphic," which conveys no idea regarding the functional or physiologic response of a living test object to the action of a chemical compound, and yet it is this physiologic effect of chemical groups in which we, as pharmacologists, are primarily interested. The physiologic effect of chemicals, or their "drug" action, is often spoken of as pharmacodynamics, and for this reason, on sound philological grounds, as well as in the interest of scientific accuracy, I have applied to the particular subject under discussion—that is, to the relationship of chemical structure to pharmacologic action—the term chemopharmacodynamics and the adjective derived therefrom, chemopharmacodynamic. Thus, for instance, the title of a recent paper by Macht and Harden in the *Journal of Pharmacology and Experimental Therapeutics* (47:377 [April] 1933) is 'Comparative Pharmacology of Some Condensation Products of Phenols with Aliphatic Aldehydes. An Inquiry into Chemopharmacodynamic Relationships.' Again, in the *Journal of Pharmacology and Experimental Therapeutics* for January 1934, the title of a paper by Macht and Davis reads "Toxicity of Alpha- and Beta-Nicotines and Nornicotines. An Inquiry into Chemopharmacodynamic Relationships." Although rather clumsy and excessively long, this word, in my opinion, does express more accurately the idea Dr. Leake intends to convey. The old word "chemotherapy," as employed by Ehrlich in a very restricted sense, is being slowly extended to denote and connote much more than is comprehended in *therapia sterilisans magna*. There is no valid reason in modern experimental therapeutics for not applying the term chemotherapy to every clear-cut pharmacologic effect produced by a definite chemical compound on a specific physiologic function, and this is the sense in which the word is employed by modern investigators as, for instance, in the "Handbook of Chemotherapy," by Fischl and Schlossberger, the first volume of which has recently been translated into English by Schwartzman (H. G. Roebuck and Son, publishers, Baltimore).

DAVID I. MACHT, M.D., Baltimore

USE OF OPIUM IN THE COMMON COLD

To the Editor—It might be of interest to the readers of THE JOURNAL to know that De Quincey made somewhat the same observations as were mentioned in the article on the medicinal treatment of the common cold, by Diehl (THE JOURNAL, Dec 23, 1933, p. 2042).

Concerning the use of morphine and its effect on acute colds sometime about 1800, he said: 'It is remarkable, also, that during the whole period of years through which I had taken opium, I had never once caught cold, as the phrase is, nor even the slightest cough.' After stopping the use of morphine, he wrote: "Now a violent cold attacked me with a cough soon after."

This quotation is from De Quincey's "Confessions of an English Opium Eater," published by the Internationale Bibliothek Berlin West 66, volume 9, page 292 and was called to my attention by the head nurse at the Murphy Memorial Hospital in this city, Miss Mary L. Wright.

M. F. MCCARTHY, M.D., Cincinnati

Queries and Minor Notes

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address but these will be omitted, on request.

TOXICITY OF CINCHOPHEN

To the Editor—I have a patient a man aged 55, who was suffering from lumbago and for whom I prescribed atophan four tablets a day. Suddenly he developed a severe urticaria with swelling of the wrist joints. A few days later typical joint pains set in and the temperature was 101 F. Was this all a typical reaction from atophan, or might it have been inflammatory rheumatism? I felt that the urticaria and swelling could be explained on that basis but the joint pains which have persisted have puzzled me. Are atophan and cinchophen identical in their action and toxicity? WILLARD P. BOWSER, M.D., Berea, Ohio.

ANSWER—Cinchophen is the U. S. P. name for the product originally introduced under the trade name Atophan. Atophan costs much more than the identical substance sold as cinchophen. Similarly, neocinchophen (ethylmethylphenylquinolinicarboxylic acid) is sold under trade names of "tolysin" and "novatophan."

In gout, cinchophen or its derivatives frequently are highly effective. In chronic arthritis or acute rheumatic fever arthralgias and myalgias these products are seldom as effective as the salicylates. In the last few years, clinical data have accumulated to indicate that cinchophen is a very toxic drug, causing serious damage particularly to the kidneys and liver. Numerous instances of injury to the liver, ranging from mild jaundice to fatal acute yellow atrophy, have been reported. Many physicians have ceased the use of this drug entirely. Allergic reactions of the nature of urticaria, dermatitis, abdominal pain and joint pains occur fairly frequently. In the latter respect this reaction does not differ from that of many other drugs, such as the salicylates.

In the particular case cited in the query, the symptoms of joint pains, urticaria and fever speak for an allergic reaction. In all probability this was due to the atophan. It is also possible for an allergic response of this type to occur as a result of bacterial allergy, such as streptococcal sore throat. The details of this case would justify the suspicion that the probable course of events were: first, an allergic reaction due to atophan, followed by an arthritis of infectious origin, which had been in the process of developing.

INFECTION WITH TUBERCULOSIS

To the Editor—I was taught that a tuberculous infection in older adults say 40 years of age or more is the result of infection received in infancy, harbored all this time but unable to develop until body resistance happens to be lowered as following some intercurrent ailment. Is this theory exploded? Please explain briefly the latest theory on tuberculous infections and give reference books or articles. Please omit name.

M.D., Iowa.

ANSWER—Probably many of the tuberculous infections manifested by positive tuberculin reactions in adults of 40 years or more were contracted in infancy or childhood. However, it is also possible that the individual received his first infection during a subsequent year of life. Forty years or more ago, little was done to prevent infants and children from becoming contaminated with tubercle bacilli.

Today the number of open foci of tuberculosis, both in cattle and in man, is relatively small. Area testing of cattle and slaughter of the positive tuberculin reactors has greatly reduced the possibilities of contamination of infants and children with the bovine type of tubercle bacilli. Moreover, pasteurization ordinances in cities have been effective. The reverse was true forty years ago. Large numbers of human cases of tuberculosis have been isolated; many of these persons have been taught how to prevent the spread of their bacilli, and recent advances in collapse therapy have closed off many lesions, so that they do not disseminate tubercle bacilli. Isolation was not practiced on a large scale, and the present-day methods of treating pulmonary tuberculosis by collapse therapy, such as artificial pneumothorax, phrenic exeresis and extrapleural thoracoplasty, had not been introduced in this country forty years ago. Therefore large numbers of infants and children were contaminated with both the human and the bovine type of tubercle bacilli formerly, whereas today in many communities the vast majority do not become contaminated until adult life is reached. Many may even pass through adult life without infection.

The first infection with tubercle bacilli is tolerated well by the human body. In fact, it brings the vast majority of the

lesions produced by the first infection under control without the appearance of any outward manifestations of tuberculosis. If the person is adult, he apparently develops the same benign first infection type of disease as he would have from infection in infancy or childhood. As the first infection type of lesion develops, the tissues of the body become sensitive or allergic to the protein fraction of the tubercle bacillus and thereafter react positively to tuberculin which contains this fraction. It is possible that allergy may eventually disappear in some individuals, but the percentage is not known. Unfortunately, this allergy, like allergy to ragweed pollen, makes further exposure dangerous to the individual, whether an infant, child or adult. While he may be able to tolerate some exposure to tubercle bacilli, just as the hay fever patient may tolerate some ragweed pollen, he falls ill from a clinical type of tuberculosis if the exposure is too great.

The ultimate goal is to reduce the number of foci of tuberculosis so that the vast majority of people will pass through infancy, childhood and even adult life without contamination. It is becoming possible to avoid outside sources of exposure to tubercle bacilli, but unfortunately the bacilli which cause the first infection type of disease often remain alive and virulent in the original focus and in the regional lymph nodes over a long period, even for the lifetime of the individual. These at any time may escape into the blood stream, the bronchial tree or elsewhere and set up a reinfection type of tuberculosis. It is not known why these bacilli escape in some cases and not in others, that is, why the caseous material burrows into a blood vessel or a bronchial ramification in one case and not in another. In any event, once tubercle bacilli are allowed to enter the body and set up foci of disease, thereafter one is at their mercy. The fortunate fact is that the capsules surrounding them are adequate in the majority of cases.

PROSTATITIS AND PROSTATIC HYPERTROPHY

To the Editor—A white man aged 27, married since Oct 11 1933 suffered from weak and dizzy spells almost every day and sometimes several times a day. He has had these attacks on and off for the past three years but they had been getting worse for the three weeks previous to his coming to see me. The attacks consist of feeling vertigo for a few minutes with black spots in front of the eyes. Then he feels weak. He has never fainted or felt nauseated. He went to a physician two and one half years ago who informed him that he had an enlarged prostate and he had the prostate massaged a few times but soon gave this up. He had had an occasional feeling of fullness in the perineum. He also has frequency of urination in the morning. The appetite and bowels are normal. There is no discharge from the urethra. I examined him and could find nothing wrong except an enlarged prostate gland more than twice the normal size the right lobe being much larger than the left. The gland was rather sensitive to pressure of the finger. Urinalysis gave normal results. The blood pressure is 125 systolic 70 diastolic. I have continued to massage the prostate at intervals of three or four days since. The patient appears to be improving, the frequency of urination has disappeared and he is able to begin urination without any delay. However, the prostate is still enlarged and is still somewhat tender to the touch. It has improved somewhat in these respects but not sufficiently to make me feel satisfied. Besides massage I have passed sounds through the urethra and have also instilled weak silver nitrate solutions into the prostatic urethra. There is no history of gonorrhea or any other venereal disease. I am at a loss as to how to explain the chronic prostatitis. The only fact I can lay my hand on is that the patient told me he had a prolonged engagement with his wife, whom he married about three years ago. This engagement lasted about three years and he was constantly aroused sexually without gratification. Can this be a cause of chronic prostatitis? I would appreciate your telling me of a plan of treating an enlarged prostate such as this. Will you be good enough to tell me also whether I can expect to reduce the size of the gland?

M D New York

ANSWER—The attacks of vertigo, with black spots in front of the patient's eyes are probably not due to disease in the prostate gland. They may be due to migraine, petit mal or some disturbance of the eyes, and this part of his complaints should be investigated by a medical man or an eye man or both. The fullness in the perineum and the frequency of urination are best explained by the presence of the enlarged prostate.

It is not quite clear from the evidence submitted whether the enlargement is due to a chronic prostatitis or to a congestion of the prostate since no information is given regarding the character of the prostatic strippings. If a microscopic examination of the prostatic strippings shows the presence of pus the diagnosis of chronic prostatitis is justified.

Chronic prostatitis may be due to many causes other than gonorrhea, such as a metastatic infection of the prostate from acute grip or acute tonsillitis and occasionally from chronic foci of infection, such as the teeth and sinuses. If the patient has chronic prostatitis it might be well to advise the use of heat by rectum by means of a prostatic heater either an electric heater or the hot water heater or one may resort to hot

rectal irrigation or sitz baths. In this particular case it might be advisable to discontinue the use of silver nitrate. The massage may be given twice a week and, later on as improvement sets in, once a week, and finally every ten days until the strippings are free from pus on microscopic examination.

On the other hand, the enlargement of the prostate may be due to bad sexual relations, such as prolonging the act or withdrawing without ejaculation. Bad sexual hygiene is suggested in this case by the statement of the long engagement with much sexual excitement and no sexual gratification. Bad sexual practices often lead to serious prostatic disturbances. If the enlargement in this case is due to any one of these causes, it must be corrected.

If the patient's prostatic enlargement is due either to chronic prostatitis or to bad sexual hygiene, the size of the prostate will return to normal with the treatment that has been outlined.

Finally, if the treatment as outlined fails to relieve the patient and the prostate does not return to its normal size, one must think of the possibility of some unusual lesion of the prostate, as, for example, a sarcoma, because of the age of the patient and failure of treatment.

STERILITY—DYSMENORRHEA—PRURITUS VULVAE

To the Editor—1 A woman aged 36, married for sixteen years and sterile had a dilation and curettage eight years ago without relief of sterility or dysmenorrhea (the patient has low abdominal cramps the first day and flows three days). Physical examination reveals a projection from the anterior lip of the cervix the size of an orange seed and of the same color and consistency as the remainder of the cervix. The uterus is acutely ante flexed. How should this small projection be removed for biopsy? Are there any other procedures that would help the sterility and dysmenorrhea other than dilation of the cervix? 2 The patient has had marked intermittent pruritus vulvae for eight years and occasional burning micturition. The urine is normal except for high specific gravity (1.030) and a pink dusty sediment consisting of the urates. The vulva shows many fine fissures and abrasions from scratching. How could the uric acid sediment be decreased or eliminated? The patient consumes about half a pint of alcoholic liquor during the week. Should this be eliminated? The pruritus is relieved by a cleansing douche for about twenty four to thirty six hours but there is no vaginal discharge. Does this suggest anything as to etiology? Please omit name and address.

M D, Massachusetts

ANSWER—1 The growth on the cervix may be a small fibroid, a malignant growth or a benign tumor resulting from manipulation with a tenaculum. The correct diagnosis in most of these conditions can usually be made with the naked eye but, regardless of this, the entire mass should be removed. This may be done with a sharp knife or an electrical cautery but, regardless of which method is used, the incision for removal should be made at least one eighth inch all round the mass. In steadying the growth during its removal, one should not use an instrument that will crush it, even lightly. Allis forceps are suitable for holding the mass. After removal of the tumor with a knife, it is nearly always necessary to suture the edges of the cervix, but if the cautery is used, this is generally not needed. The tumor should, of course, be subjected to microscopic examination without delay. Most likely the projection is a benign one due to manipulation of an instrument such as a vulsellum or tenaculum. Usually these nodules are cystic and contain blood. They frequently are mistaken for carcinoma, especially because they may recur after removal.

Sterility, dysmenorrhea and pruritus vulvae are the three most baffling problems in gynecology and all usually require intensive study. In the cases of sterility and dysmenorrhea this includes not only a careful physical examination but also an investigation of the patient's past history. The combination is frequently found in women who have underdevelopment of the uterus. For the relief of the sterility it is essential to be certain that the husband's spermatozoa are satisfactory from the point of view of number, motility and normal contour. If the semen examination is satisfactory and no abnormalities are found on bimanual examination of the woman, a Rubin tubal insufflation test should be performed. This test often relieves dysmenorrhea. If the tubes are impermeable to gas, especially on repeated examinations and after the use of atropine to relax a possible spasm of the uterotubal junctions, iodized oil should be used to determine the site of obstruction. If a block is found, an operation may be performed to relieve this, but the chances for a pregnancy are not good, especially in a woman 36 years old who has been sterile for sixteen years. If the tubes are patent, it may be necessary to regulate the diet of both the wife and the husband to explain the most favorable time for conception, and to give other information. Recently endocrine preparations have been used successfully in some cases of dysmenorrhea and sterility but thus far the results have been too inconsistent to recommend them.

2 Evidently the pruritus of the vulva in this case is not serious or it would have been associated with marked and perhaps ominous changes in the vulva and labia after a period of eight years. Stubborn itching in this region is frequently associated with leukoplakia, which in many cases leads to the development of carcinoma. Since examination of the urine is negative, diabetes may be ruled out. Since there is no vaginal discharge, *Trichomonas vaginalis* and monilia may be eliminated as causes. However, because douches give relief, a hanging drop examination should be made of some of the vaginal secretion and, if any abnormal organism is found, appropriate treatment should be instituted. Alcohol should be eliminated for a time to see what effect this will have. Simple cleansing with a mild soap and water may suffice to give relief and the occasional local application of a weak silver nitrate solution may help.

GRANULOMA INGUINALE AND LYMPHOGRANULOMA INGUINALE

To the Editor—Please enlighten me on the differential diagnosis, etiology, pathogenesis, treatment and prognosis of granuloma inguinale (Donovan bodies) and lymphogranuloma inguinale (Frei test). The more I read the current literature the more confused I become. Please omit name.

MD New York

ANSWER—Granuloma inguinale and lymphogranuloma inguinale have but two points of resemblance. They are both classed as venereal diseases and, unfortunately, they have names that are so much alike that they are confusing. Otherwise the diseases are totally dissimilar.

Granuloma inguinale is due to inclusion bodies at present called Donovan bodies. There is some discussion in regard to what these inclusion bodies are, but, for the purposes of a short reply, the use of the term Donovan bodies is sufficient.

Lymphogranuloma inguinale, on the other hand, is due to a filterable virus that can be transferred to several of the lower animals by way of subdural injections causing an encephalitis. The incubation period of lymphogranuloma inguinale is from one to two or three weeks. The exact incubation period for granuloma inguinale is not exactly known but probably varies from a few weeks to a month.

With lymphogranuloma inguinale there may be a primary lesion of the type of a papule or a pustule, of herpetic process or of a specific urethritis which may be confused with gonorrhea. Following this primary lesion which is usually evanescent in character, there is an involvement of the draining lymph nodes. The adenitis of lymphogranuloma inguinale is characteristic. The nodes in a chain become fused together in a large mass, which may reach half the size of a fist, and then the process breaks down with multiple fistulous openings. Along with the local adenitis there may be systemic symptoms of malaise, loss of appetite, loss of weight, rheumatic symptoms, eruptions on the skin, and a temperature elevation which may be of the intermittent remittent or continuous type. Occasionally the elevation of temperature will persist over a long period, successive flare ups accompanying the involvement of fresh lymph nodes.

In the female affected with lymphogranuloma inguinale the picture may be somewhat different owing to the fact that most of the lymph channels running from the vulva drain into the nodes around the lower part of the rectum, resulting in an inflammatory reaction of these nodes and a secondary involvement of the rectal wall. It has been found that certain of these female cases, as a result of the local process later present an inflammatory stricture of the lower rectal walls, which may be annular or tubular in character. Rarely in a female, along with a stricture of the rectum there may be excrescences developed round the anal orifice sometimes accompanied with fistulas, and there may also be more or less elephantiasis of the vulva and fistula formation going under the term *esthiomene*.

Clinically there should be no difficulty in making a differential diagnosis between granuloma inguinale and lymphogranuloma inguinale. Lymphogranuloma inguinale is essentially a disease of the lymph channels and of the lymph nodes, while granuloma inguinale is a disease affecting the skin itself, there is never an involvement of the lymph nodes in granuloma inguinale. In the latter disease one finds a beefy red generally somewhat raised rather rugose, moist proliferation of the tissues which is most characteristic in appearance. Instead of spreading by the lymph nodes, the disease spreads by contiguity and may spread by contact from the genitalia to the inside of the thighs. Or the process may spread from the genitalia down over the perineum and perhaps up into both groins by way of the skin. At no time however will there be an involvement of the nodes themselves. As a rule there

are no systemic symptoms in connection with granuloma inguinale. One is assisted greatly in making a diagnosis of granuloma inguinale through making a smear from the local inflammatory tissue or removing a specimen of the tissue and making a smear on a glass slide with the undersurface of this tissue, the same as one would make a blood smear. The slide is then stained with either Giemsa's stain or Wright's stain and specific Donovan inclusion bodies will be found, though probably with some difficulty unless the physician is accustomed to the microscopic picture. One is assisted in making a diagnosis of lymphogranuloma inguinale by the so called Frei test. This is a specific intradermal test performed the same as one makes a tuberculin test. The antigen consists of some of the sterilized pus taken from a bubo just before it is going to break down. Naturally, a test could not be made with pus taken from the patient who is to be tested. One tenth cubic centimeter of this material is injected intradermally, and in forty eight hours there will be a raised erythematous tubercle, from 0.5 to 1 cm in diameter in a positive case.

The prognosis and outlook in either of these diseases is some what guarded owing to the fact that in granuloma inguinale there is such a frequent tendency for recurrence and that in lymphogranuloma inguinale one of the serious complications such as stricture of the rectum, may result before the disease is finally cured. It is true, however, that once lymphogranuloma inguinale is cured the patient ordinarily has no further difficulty and it is a question whether he is not immune for the rest of his life. Strangely enough antimony seems to be the best preparation for treatment of either of these diseases. In the past this has been used in the form of antimony and potassium tartrate, a 1 per cent solution being employed and an injection given intravenously of 3 cc plus 7 cc of saline solution. The antimony and potassium tartrate is stepped up 1 cc at a dose the injections being given once in three or four days until a maximum dose of 10 cc of the 1 per cent solution is given and this may be continued for ten to fifteen or more injections, the kidneys being watched for evidence of irritation. Recently a new antimony preparation Fuadin has come on the market (*THE JOURNAL* May 27, 1933, p. 1685). Fuadin is much easier to administer since it may be given intramuscularly and with little discomfort to the patient. The injections are given once in two or three days starting with a dose of 2 cc and working up to a maximum dose of 5 cc, a total of from 45 to 50 cc of the preparation being given which constitutes a course. A course may be repeated within a month if found necessary. With a case of lymphogranuloma inguinale rest in bed is quite essential, and it may be necessary that some minor surgical procedure such as opening necrosing lymph nodes or even partial removal of a broken down lymph node, may be necessary.

CYANOSIS OF FINGER NAILS

To the Editor—In what conditions other than cardiac decompensation and pneumonia is cyanosis of the finger nails of clinical significance? Please omit name.

MD Pennsylvania

ANSWER—Cyanosis of the finger nails may be part of the picture of general cyanosis on the basis of inadequate oxygen saturation of the blood, or it may result from various types of local venous stasis.

General cyanosis is often the result of disease of the oxygenating organs, i. e., the lungs. In this event, sufficient oxygen is not available to the blood. In addition to the acute conditions mentioned, certain chronic diseases in various stages of their evolution exhibit more or less cyanosis. Examples of this group include hypertrophic emphysema, chronic bronchitis, bronchial asthma, pulmonary neoplasms and sclerosis or syphilis of the pulmonary artery and its branches, or Ajerza's disease.

Cardiac decompensation and other conditions, occasionally hypertension with early left ventricular failure, result in pulmonary stasis. Congenital malformations of the heart or great blood vessels with shunt of the blood flow in part past the lungs will result in inadequate oxygenation and cyanosis.

In many of these conditions, compensatory types of polycythemia occur in the effort to supply greater oxygen carrying capacity to the blood for the existing oxygen want. This only results in incomplete oxygenation of a greater amount of hemoglobin. Likewise, such diseases of the blood as polycythemia vera cause cyanosis because the total amount of hemoglobin is so great that it cannot be completely oxygenated. Cyanosis is but rarely seen in severe anemia.

Intoxication often results in stable compounds of hemoglobin, which cannot be readily oxidized. Poisoning with gaseous compounds of sulphur, particularly hydrogen sulphide, with the formation of sulphhemoglobin show marked cyanosis. Acetanilid

poisoning is another common example of cyanosis of this type. Carbon monoxide is a similar poison, but instead of cyanosis the color imparted to the skin is a cherry red, cyanosis may occur. Likewise, asphyxia by inert gases or tracheal obstruction may cause temporary cyanosis. Carbon dioxide and nitrogen compound gases are examples.

Local venous stasis involving the upper extremities may occur as the result of pressure on the veins from extravascular causes, of which mediastinal tumors or aneurysm interfering with the flow of blood in the superior vena cava is an example. Intravascular causes are arteriovenous aneurysm, thrombosis and thrombophlebitis.

In functional circulatory disorders such as the stage of asphyxia in Raynaud's disease, cyanosis is present. It also occurs in acrocyanosis, for which Layang believes that a functional stasis in the venules is responsible. The hands are involved, they are cold and moist and purplish red rather than a definite blue.

TREATMENT OF GONORRHEA

To the Editor—I have under my care a young graduate nurse who says that she has had a profuse purulent vaginal discharge for at least six months. The smear is positive for gonococci. The vaginal mucosa is intensely inflamed looking while the membrane covering the cervix looks as though it were absent entirely, with a raw looking surface which bleeds easily. There is a purulent looking discharge oozing from the urethra although the patient says it is only rarely that she has any discomfort on urinating. Besides this she has a four plus Wassermann and a positive Kahn reaction. In regard to the treatment of this case to douche or not to douche if so with what solution? Vaccines for the gonorrheal infection? Any injections into the urethra while the discharge is so profuse seems too dangerous. She has no symptoms from her syphilis that I can find except palpable inguinal and epitrochlear glands. There is no history of chancre or indolent sore. There is no eruption. Please give as full directions as possible for the latest treatment for both these conditions and any special treatment for the combination if there is such. The patient is busy most of the time. How about her resting? How many intravenous treatments would she have before she takes another case in justice to her patients? Also please omit name if you answer this in THE JOURNAL.

M D Pennsylvania

ANSWER—It is not stated whether there is palpable evidence of infection of the upper pelvic zone, so it is assumed that the tubes and ovaries are normal.

Active antisyphilitic treatment should be instituted at once. It will be impossible to determine how much of the trouble is ascribable to gonorrhea until the results of antisyphilitic treatment are evident. Rest in bed is almost imperative.

There is no great objection to douches in a case such as this provided the douches are given gently, without undue force. It should be understood, however, that douches have little therapeutic value. They are of help chiefly in keeping the parts clean and in making the patient more comfortable. The Elliott method (Holden, F C, and Gurnee W S. *Am J Obst & Gynec* 22:87 [July] 1931) would probably be beneficial in this case but, if used great care will be required to avoid heat sufficient to produce necrosis.

In general, nonsurgical care of the gonorrheal infection is indicated, at least until all active symptoms have subsided. But search should be made for hidden foci of infection, particularly pus pockets in Skene's ducts and blocked drainage from the cervix. (Passage of a dilator beyond the internal os in a patient with such virulent infection of the lower genital tract is rather hazardous.)

The value of specific therapy has not yet been demonstrated. Despite the fact that use of vaccines and the injection of sterile milk and other foreign proteins have many warm advocates, the efficacy of these remedies is open to serious question.

POISONOUS SAFETY MATCHES

To the Editor—I note that in 1913 an act was passed placing a prohibitive tax on poisonous matches. Several cases have come to my notice lately of infants eating the heads of both safety matches and of the self-igniting sorts. Are there any poisonous matches obtainable at retail? How many match heads may be safely consumed by a year old infant?

S A BRITEN, M D Syracuse N Y

ANSWER—The elimination of white phosphorus from the match industry in this country went far toward protecting the match maker against industrial poisoning but by no means freed the public from the dangers following the ingestion of match heads.

Phosphorus is not the only toxic agent entering some matches and certain instances of poisoning must be attributed to other constituents, such as antimony compounds. Safety matches are likely to contain phosphoric acid, sulphur, potassium chlorate, zinc carbonate, antimony compounds, powdered glass and glue. The striking surface may contain red phosphorus.

At the present time "strike anywhere" matches are likely to contain phosphorus sesquisulphide along with potassium chlorate, zinc oxide, ochre, powdered glass, paraffin and glue.

Red phosphorus and the sesquisulphide may retain some white phosphorus as an impurity (0.6 per cent). Although the tax regulation of 1913 practically eliminated the use of white phosphorus, it cannot be said that all exposure has been eliminated.

Tourists returning from Europe may innocently bring with them casual supplies of matches from countries tolerating the use of white phosphorus.

In a standard work on toxicology in this country, published in 1923, the following statement is found: "The Lucifer matches commonly sold are tipped with waxy or poisonous phosphorus mixed with potassium chlorate, sand and glass, but the safety match is tipped with potassium chlorate and antimony sulphide, without phosphorus."

Poisoning after ingesting safety matches is probably traceable to antimony. Cases from "strike anywhere" matches are probably traceable to phosphorus sesquisulphide or to white phosphorus present as an impurity.

No match heads can be safely consumed by a year old infant. Two match heads ingested by a child are said to have caused death. This low figure should not be accepted as necessarily dangerous as other instances are known wherein scores of matches were sucked or ingested without fatal results.

UROTEX

To the Editor—What is Urotex? I assume you have others of this same company. However I am enclosing one of the many sheets I have received from this particular company.

M D Seattle

ANSWER—Enclosed by our correspondent was a carton for Urotex, together with a circular letter addressed to the physician asking for case reports. According to the formula on the label, Urotex consists of two tablets, A and B. The formula for tablet A (gray) is as follows:

Hexamethylenamine	2½ gr
Ext. Nux Vomica	½ gr
Acid Benzoic	¼ gr
Atropine Sulphate	1600 gr
Excipients and coating	q s

The formula for tablet B (brown) is as follows:

Ext. Buchu 14	½ gr
Ext. Corn Silk 15	¼ gr
Ext. Triticum 13	¼ gr
Pot. Bicarbonate	1 gr
Sodium Borate	½ gr
Caffeine	⅛ gr
Atropine Sulphate	1600 gr
Excipients and coating	q s

These formulas of course, are an insult to the intelligence of the medical profession. They represent the shotgun type of proprietary sold to physicians in the period preceding 1906 except that the composition appears on the label.

The carton also contains therapeutic recommendations, so that the physician who prescribed the product would simply be serving as an advertising tool in the hands of the manufacturer.

The product has not been submitted to the Council on Pharmacy and Chemistry for consideration. It goes without saying, however, that the Council would not approve such a product.

The circular letter addressed to the physician is an imposition and an affront. Note the following paragraphs, for example:

"I would like to have 100 case reports on Urotex to report to physicians of your state. So far I have 37 reports from your state. I would like to have 63 more."

"That brings me to the favor I have to ask of you. I would just like to have you tell me what results you have had with Urotex. (Your name will be held in confidence, if you desire.)"

Surely thinking physicians would not permit their names to be used in the promotion of such an unscientific mixture.

PHOTOSYNTHESIS

To the Editor—I have been searching for an explanation of the process of photosynthesis. There are several theories which are not convincing. The subject is either sidestepped or ignored by such authors as McCollum, McLester, Sherman, Parsons and Lusk. Will you kindly give me the latest information on the subject and state which theory is considered the most tenable?

N PHILIP NORMAN, M D New York

ANSWER—There are no theories which adequately or in accepted detail explain the processes of photosynthesis in plants or, for example, the mechanism whereby certain substances may become possessed of antirachitic power by ultraviolet irradiation. Probably it is the formation of vitamin D from the ergosterol in the skin that accounts for the antirachitic action.

of ultraviolet rays In the light of modern theories of matter and energy (Einstein, Planck and Bohr) it is postulated that the absorption of energy produces changes in either electronic or molecular activity Probably before any reaction of this character can take place the substances taking part in it must acquire a certain amount of extra energy The activated molecules do not lose their energy increment on combining but produce an activated compound that is capable of imparting its energy to other molecules Inert molecules are closed systems, energized atoms and molecules are systems that are opened up and react Fundamentally the activation of inert atoms and molecules may be conceived of as being due to radiant energy, which, when absorbed, ionizes or energizes atoms (that is, either causes an addition or subtraction of an electron or changes the energy level of an electron according to the Bohr theory), initiates chemical reactions or so changes molecular configurations as to endow them with new activities or properties

URTICARIA AFTER USE OF PITUITARY PREPARATION

To the Editor—I have a patient who apparently had an endometrial hyperphasia and who was treated with Antutrin S with complete relief Following the last injection about three weeks ago she had apparently a redness around the site of the injection This was followed about two days later by giant urticaria which has persisted clearing and recurring every day I have treated her by hypodermic injections of epinephrine 8 minims (0.5 cc) twice daily along with three eighths grain (0.025 Gm) of ephedrine three times daily Could you suggest more efficient therapy? How much longer is it possible for this annoying condition to exist? Would theelin or any other ovarian preparation be indicated? Please omit name

M D, California

ANSWER—The urticaria is most likely due to some substance in the "Antutrin-S" to which the patient is hypersensitive, or to some product produced by the Antutrin-S at the site of injection The Council on Pharmacy and Chemistry has accepted no "ovarian" preparation (See report on Estrogenic Substances Theelin, *THE JOURNAL*, April 29, 1933, p 1331) The manufacturers of Antutrin-S are still doing experimental development work and have therefore delayed submission of the product to the Council If there is a small abscess at the place of the last injection, this should be opened and drained Otherwise there is no specific remedy The effects of Antutrin-S and similar substances are nearly always temporary, because these substances are usually substitutional in character Hence the untoward effects, just like the beneficial ones, should soon wear off Of course, a search should be made for some other source of the urticaria, for it is possible that the sequential occurrence of this troublesome symptom and the injection of Antutrin-S may have been accidental It is not known whether theelin or other ovarian preparations will overcome the urticaria

ETIOLOGY OF DIABETES

To the Editor—I am anxious to collect some data on the etiologic factors in diabetes mellitus A physician aged 65 has suffered from diabetes mellitus for a period of fifteen years He enlisted in the United States Army in 1917 Up to that time he had enjoyed perfect health The previous history was negative except for diseases of infancy Thirteen months after he enlisted glycosuria appeared Further investigation proved the cause to be diabetes mellitus The family history is negative as to diabetes The change from hospital practice to military duties involved considerable increase in work and effort During the period of enlistment the patient was under constant strain both physical and mental What is the general view as to the part played by overwork and mental stress in the causation of diabetes? Can you refer me to authorities on the etiology of diabetes mellitus? Please omit name and address

M D California

ANSWER—The commonest years for the onset of diabetes in men are between 51 and 53 Decrease of work and effort are more apt to precede the onset of diabetes than the reverse Physical and mental strain such as occurred in the German and American armies did not appear to favor diabetes, according to German and American authorities The following references may be consulted

TOXICITY OF DINITROPHENOL

To the Editor—I have been following the recent literature on the use of dinitrophenol in obesity with interest Has any work been done to determine its mode of excretion or destruction in the body? Likewise what are the possibilities of its storage in or deleterious effect on the liver, such as is known to occur with trinitrophenol? When such a drug as cinchophen is used one is at least fully aware of the possibility of damage to the liver Can as much be said for dinitrophenol or are we still wholly in the dark? Please omit name

M D New York

ANSWER—Dinitrophenol appears in the urine promptly and is rapidly excreted, probably within one or two days after administration Its fate in the body is not certain, but possibly a part is converted to the less toxic aminodinitrophenol Continuous administration for as long as six months has not resulted in perceptible harm to the liver or other vital organs The only alleged liver damage so far reported in patients is one case in which a physician undoubtedly mistook the yellow color of the dye dinitrophenol for bile pigments In this case the supposed evidence of liver injury disappeared at once when the drug was discontinued So far it is not known whether continuous administration over periods of years might be harmful, but it is significant that workers engaged in making it during the war, when there was continuous exposure for several years at a time did not show evidence of injury to the liver or other vital organs

EATING OF CANDY BY CARDIAC PATIENT

To the Editor—Please advise me as to whether there is any contra indication to giving candy in small quantities to a cardiac patient who is in a state of decompensation Kindly omit name

M D Michigan

ANSWER—There is not only no contraindication to giving candy in small quantities to cardiac patients but good reasons for giving it, so long as the candy is in a digestible form All muscle needs an abundant supply of carbohydrate for its metabolism and this is especially true of the heart muscle the needs of which are greater than those of the other muscles

TREATMENT OF RECTAL GONORRHEA

To the Editor—In *THE JOURNAL* Dec 23 1933 page 2069 is a query regarding the treatment of rectal gonorrhea In the answer given to the doctor from West Virginia no mention is made of the use of diathermy in the treatment of the urethral and cervical infection Because of this fact I am writing to bring this omission to your attention as the method first described by Dr Elkin P Cumberbatch who is director of electrotherapeutics at St Bartholomew's Hospital in London has proved to be a definite advance in the treatment of gonorrhea in women Dr Cumberbatch has been doing this work for over fifteen years and published a book on the subject which probably has not been widely read in this country I have been using his technique for about ten years with phenomenal success and we at the Medical Center in New York have used it as a routine procedure in all cases I can most highly recommend this technique from actual experience in a large number of cases which will be reported from our clinic next year and on behalf of my interest in physical therapy I think that some recognition of the effect of diathermy in these conditions should be given in the answers to queries that come in to *THE JOURNAL* As a pretty good proof of the action of this form of treatment, I have had one case of rectal gonorrhea in which there was no infection of the urethra cervix or vagina I treated this patient for about a month attempting to clear up the rectal infection with similar technique and made definite progress During all this period there was no transference of the infection interiorly which would strongly point to the fact that as she got the Cumberbatch method of diathermy to the urethra and cervix this procedure was able to keep the cervical canal free of infection On the advice of her family the patient went to another doctor who guaranteed a cure and within two weeks she had a virulent cervical and urethral infection This later spread into the tubes and the patient had to have one removed The effectiveness in keeping the anterior parts clean during the time she was under my observation should be definite evidence as to the effectiveness of the heat created by the Cumberbatch technique

NORMAN E TITUS M D, New York

SENSITIVITY TO EPHEDRINE

To the Editor—I should like to add to the answer in *THE JOURNAL* January 6 page 67 to the query on the possible ill effects from ephedrine In addition to other evidences of sensitization skin eruptions sometimes of a very extensive nature may develop (Abramowitz E W and Noun M H *Ephedrine Dermatoses Clinical and Experimental Study of a Personal Case with a Review of the Literature Brit J Dermat & Syph* 45 225 [June] 1933)

E WILLIAM ABRAMOWITZ M D New York

PREPUTIAL INFLAMMATION

To the Editor—Several inquiries have appeared regarding preputial inflammation Many of these cases are due to fungi and are easily cured by frequent application of sodium thiosulphate 10 per cent solution

The Principles of Treatment of Muscles and Joints by Graduated Muscular Contractions. By Vinton Smart C.A.O. D.S.O. M.D. Cloth Price \$3.75 Pp 217 with 4 illustrations New York & London Oxford University Press 1933

The object of this book is to present the treatment of injuries to muscles and joints and their sequelae by the method of graduated muscular contractions and to describe the electrical unit used and the technic of its application. The author emphasizes the importance of the restoration of muscle function after all types of injuries. He calls attention to the fact that when a joint is injured nearly every other component part receives some kind of treatment. While graduated muscular contraction treatment is not new, it was popularized by the author. A muscle, he points out, is a highly sensitive structure with power to respond to a variety of stimuli and when in a healthy state is capable, by its tone and its inherent power to contract, of acting as a guard to a joint by intercepting any sudden stresses that might cause damage to other joint structures. A knowledge of physiology is therefore essential to the study and treatment of injuries to muscles and joint structures. Although graduated muscular contractions are produced by means of an electric current it must be understood that no virtue of curative power whatever is claimed from the use of electricity per se. In the foreword, William O'Neill Sherman says that graduated muscular contraction is the greatest advance in physical therapy since the introduction of massage as a therapeutic measure and can be used to the exclusion of the latter in the treatment of the various injuries. The method is indicated in the treatment of injuries of the soft parts, including muscle and ligament strains, sprains and hematoma, myositis, torticollis, atrophy of disuse, synovitis, periarticular adhesions, synovial adhesions and fibrous ankylosis. Sherman says that massage has been dispensed with in his clinic because of its limited value in comparison with graduated muscular contraction. He says also that the Smart unit permits of painless and graduated control of the muscle contraction from its origin to its insertion. The author has given his results with this method of treatment covering a period of thirty years of study of muscles and joints. The basic feature of the apparatus is that it permits the operator to have complete and accurate control of the strength of the stimulation throughout its whole range so that he can cause the muscle to contract and relax with accuracy of time and degree. The book contains chapters on general physiology of muscle, trauma, posture, strain, sprain, manipulation of joints and after-treatment, adhesions following injury to the shoulder joint, technic in the manipulation of the shoulder joint and description of the unit for producing graduated muscular contractions.

Diet and Personality. Fitting Food to Type and Environment. By L. Jean Bogert Ph.D. With an Introduction by Lafayette B. Mendel Ph.D. Sc.D. Sterling Professor of Physiological Chemistry in Yale University. Cloth Price \$2.10 227 New York Macmillan Company 1931

This book is intended to stress the fact that diet must be adjusted to individual conditions. It is really an elementary book of general hygiene and includes discussions of rest, sunshine and mental habits, in addition to the discussions of diet. Its title is misleading, and the subtitle even more so, although some of the chapters deal with structural types—the stocky, the slender, the underweight and the middle aged. The writers' descriptions of the personalities that go with these types are naive, and they are quite far from the beliefs of modern psychiatry. There are other chapters, which treat of such subjects as susceptibility to infections, indigestion and constipation, which, although they may affect the personality, are not of such moment, nor is their connection with it so well known, as to warrant their being included in a book supposedly on personality. The fact that the author stresses the effect of worry and strain on physical well being, and her references to the effect of improper hygiene on mental capacity, would give this book some value, and she deserves a word of praise for stressing the psychologic factors of metabolism and assimilation. Also it must be admitted that the book is easy reading. On the other hand the psychologic material is unsatisfactory. For instance, the chapter entitled "Nervous Strain. The Great American Enemy" points out the real problems of overwork and fatigue but the author suggests the elimination of worry by such broad and indefinite methods as a "change of mental habits." There is some discussion of the physiology of the body fluids as well as the nervous system, scattered throughout the book, which are satisfactory and simple. Physicians will probably find this book no more useful than the usual book of hygiene intended for the layman, psychiatrists will probably reject it because the inferences it draws have yet to be justified but some individual patients may be helped by reading certain chapters.

Once lecciones sobre el reumatismo. Por C. Marañón profesor de la Universidad Central Instituto de patología médica del Hospital General de Madrid. Paper Price 10 pesetas Pp 249 with 51 illustrations Madrid Espasa Calpe, S. A., 1933

The popular term "rheumatism" includes articular and muscular conditions. These two types are divided into subgroups on the basis of etiology—the articular into the endogenous, the exogenous, the symptomatic and those of doubtful origin. The muscular variety is the result of endogenous or exogenous agencies. There are eight lectures devoted to the articular form. The discourse on the cardio-articular, focal and symptomatic rheumatisms is the best. Of interest is the portion concerning the traumatic variety. Trauma may produce the ordinary signs and symptoms of acute articular rheumatism, but this is not a true rheumatic condition. In the chronic deforming arthritides a history of injury is often obtained. These subtypes are of great import in cases in which the question of compensation becomes paramount. There is one lecture on the muscular rheumatisms. The last lecture has to do with treatment. It is essential that the underlying cause of the disease be determined in each case so that it may be treated. In this way the best results may be obtained. Each lecture is supplemented with an extensive bibliography. There is also a helpful glossary of rheumatic terms.

The Digestive Tract. A Radiological Study of Its Anatomy, Physiology and Pathology. By Alfred E. Barclay O.B.E. M.A. M.D. Lecturer in Medical Radiology University of Cambridge. Cloth Price \$12 Pp 392 with 275 illustrations New York The Macmillan Company Cambridge The University Press 1933

This is a radiologic study of the anatomy, physiology and pathology of the digestive tract. There are also several chapters on technic. The text is written clearly. The illustrations are numerous especially is this true of the normal position of the viscera seen on fluoroscopic and plate examination. One, therefore, will be able to detect deviations from the normal. The book is to be recommended as a useful one for the office or the laboratory.

Hair Dyes Right of Court to Require Disclosure of Ingredients—The plaintiff brought suit against Inecto, Inc., and another, alleging that a hair dye manufactured by the corporation was inherently dangerous and that it injured her when it was applied to her scalp eyelashes and eyebrows. The taking of testimony before trial under certain restrictions, is sanctioned by a New York statute if such testimony is material and necessary to the plaintiff's cause of action. Acting thereunder the plaintiff served notice on the corporation that, before trial its testimony would be taken at a specified time and place, and the supreme court of New York ordered the corporation to submit to this pretrial examination and to give testimony concerning the chemicals, poisons, drugs and other ingredients of the hair dye. This order was affirmed by the appellate division, and the corporation appealed to the Court of Appeals of New York.

The plaintiff, said the Court of Appeals to succeed in her action must prove the presence of inherently dangerous and poisonous ingredients in the hair dye. *Karr v. Inecto, Inc.* 247 N. Y. 360, 160 N. E. 398. If proof of the presence of such ingredients can be obtained only by an examination of the defendant corporation, it cannot be held as a matter of law that an examination before trial is not necessary. If other methods of ascertaining the presence of the poisonous ingredients are available, the examination before trial of the corporation is not necessary. The corporation contended that if its dye contained poisonous ingredients such a fact may be established by analysis. If this be true, and the record disclosed nothing to the contrary, the court said the plaintiff does not have a right based on necessity, to examine the corporation with respect to the presence of these ingredients. The formula employed in the manufacture of the dye is property and if the secret compound contains nothing except harmless ingredients and its alleged injurious effect on the plaintiff was due to her idiosyncrasy, then the corporation's property right is entitled to preservation. Generally disclosure of legitimate trade secrets will not be required except to the extent that it appears to be indispensable for ascertaining the truth. There can be no legal sanction for the circulation of poison throughout the community, continued the court and if the dye does include inherently dangerous substances, the secrecy of its manufacture ought not to be protected. An examination of the corporation before trial however may and probably will the court said, have a tendency to disclose not only the ingredients of the dye which may be entirely harmless to the normal person, but it may also uncover other facts which might lead to destruction of valuable property rights vested in the corporation by their transfer through such a publication, to trade rivals. Since the record disclosed a total lack of evidence bearing on any necessity for an examination of the corporation before trial, both the supreme court and the appellate division were without discretionary power to order it, concluded the Court of Appeals. Accordingly the order permitting the examination was reversed. —*Drake & Herrman (N. Y.) 185 N. E. 687*

Workmen's Compensation Acts Award No Bar to Action for Malpractice—The Tennessee workmen's compensation act provides that whenever an employee has sustained an industrial injury under circumstances creating liability in some other person than the employer the employee may, at his option claim compensation from his employer or proceed at law against such other person or proceed against both the employer and such other person. He may not however collect from both. If compensation is awarded under the workmen's compensation act and the employer pays the compensation or becomes liable therefor he may collect in his own name or in the name of the injured employee from the other person against whom legal liability for damages exists the amount paid the employee. This provision said the Supreme Court of Tennessee, does not prevent an employee from suing a physician whose malpractice has aggravated his industrial injury even though the employee has previously recovered compensation from his employer by reason of a settlement, if in such settlement the

employer expressly waives his right of subrogation and if no part of the compensation paid was for loss of time and for injuries suffered by the employee because of the physician's negligence.

The workmen's compensation act continued the court was enacted for the benefit of employers and employees. It has little concern with the rights of third parties, negligent wrongdoers. The provision discussed is clearly for the benefit of the employer to prevent the employee from recovering damages from a third party and at the same time recovering compensation under the act from his employer. It gives an employer, paying compensation under the act, a right of action against the wrongdoer inflicting the damages. An employer may waive his right of subrogation and no rights of the wrongdoer are affected. The right of action against the wrongdoer accrues to the employee. The employer paying compensation may take this right of action from the employee or he may leave it with the employee. If, in a settlement between the employer and the employee, it is agreed that the right of action against the third party wrongdoer shall be left with the employee, the third party wrongdoer cannot complain. In any event, the wrongdoer can be held only for such damages as he has inflicted whether he be sued by the employer or by the employee. If the suit is by or for the employer, the statute limits recovery to the amount paid by the employer to the employee. An employee may recover full damages for the tortious injury inflicted on him by the third party.

The physician defendant in this case concluded the Supreme Court, may not question the motives that influence and the considerations that support a settlement between the employee and his employer. The physician's liability to the employee is just what it was before compensation proceedings were begun. The decision of the trial court against the employee was therefore reversed and the case remanded for further proceedings. —*Keen & Allison (Tenn.), 60 S. W. 2d 158*

Malpractice Sponge Left in Operation Wound—The plaintiff sued the defendant-physicians, alleging that they negligently left a large piece of towel or surgical gauze in his abdomen following a herniotomy and that an infection followed which incapacitated him for two years. The trial court directed a verdict for the defendants, and the plaintiff appealed to the Supreme Court of Wyoming.

At the trial a nurse, who was in charge of the hospital in which the herniotomy was performed and who attended the plaintiff, testified that she removed the dressings on the operation wound October 15 ten days after the operation and that there was stitch pus and the dressing was soiled from drainage. The wound was closed and she saw no rubber tubing or gauze in it. On October 22, she further testified, she removed from the wound a towel about 12 by 24 inches similar to the towel furnished by the hospital for use in operations. The hospital record of the daily condition of the patient, prepared by the nurse, showed an entry for that date 'Retained sponge removed'. On cross examination she stated that all dressings used in the operation were sterile. The plaintiff called both defendants for cross-examination, a procedure authorized by statute. The defendant Hilton testified that he performed the operation and that in a large percentage of cases it is bad practice for a physician to leave a foreign substance in a wound. He testified that he left no towel in the incision but that he did leave gauze drainage because of fear of pus. This constituted good practice, he said. Both he and the defendant Earle, who assisted in the operation and who was called for cross-examination under the statute testified that the leaving of a sterilized towel in a wound would not cause infection. There was no other medical testimony.

Before a plaintiff can recover for malpractice, said the Supreme Court he must show by affirmative evidence that the defendant was unskillful or negligent and that his want of skill or care caused injury to the plaintiff. If either element is lacking in the proof, the plaintiff has presented no case for the consideration of a jury. Where evidence is as consistent with the absence as with the existence of negligence the case should not be left to the jury. What is or is not common practice on the part of a physician is a question for experts and can be established only by their testimony. In the case

at bar, continued the court, claim was made that the infection resulted from the alleged failure of the defendants to remove a towel or surgical gauze from the operation wound. The burden of proof rested on the plaintiff to show that a towel or surgical gauze was negligently left in the operation wound. The testimony of the nurse was relied on to establish this fact. She was not present at the operation and did not of course know what was then done. She did testify that a towel was removed from the wound, October 22. Nevertheless, on the hospital record which she testified she made herself, she noted "Retained sponge removed." Nothing was entered about a towel. The defendant Hylton, who performed the operation, denied that any towel was left in the incision but testified that necessary gauze drainage was left. Thus this defendant's testimony, observed the court, coincided with the hospital record. If the defendant Hylton's testimony be true, then there was no proof of negligence in leaving the foreign matter in the wound. The nurse's oral testimony was in conflict with the statement in the hospital record, which she made. The jury would have been obliged to guess whether a towel or a sponge was removed from the wound. The court considered it at least doubtful whether the burden of proof was sustained by the plaintiff to show negligence on the part of the defendants.

There still remained the question, continued the court, whether the plaintiff established any causal connection between the alleged negligence and the damage suffered. Both defendants testified that a sterile towel left in a wound would not cause infection, and there was no evidence to the contrary. Furthermore, the nurse testified that all dressings used in the operation were sterile. In the absence of evidence on the subject it will be presumed that a physician or surgeon discharged his full duty to the patient, including the exercise of reasonable care and skill in his treatment. It devolved on the plaintiff in order to justify the submission of the case to the jury, to produce evidence that the towel was not sterile and this was not done. Accordingly, the Supreme Court affirmed the action of the trial court in directing a verdict for the defendant physicians—*Rosson v Hylton (Wyo)* 22 P (2d) 195.

Workmen's Compensation Acts **Compensability of Traumatic Neurosis**—On June 17, 1929, a slab of rock fell a distance of about six feet on to Sykes' shoulders and back, knocking him down. He was able to walk to a car and was taken home. Within a week he returned to work and worked until August 22 when he was compelled to quit because of severe pains in his back and neck. He remained in bed for five or six weeks under the care of a chiropractor. His left leg became partially paralyzed. His employer paid him compensation for one year. In August 1930, Sykes refused the employer's offer of light work and thereupon the employer ceased making payments. Sykes then instituted proceedings before the industrial accident board.

All the physicians who testified before the board agreed that Sykes showed symptoms of an injury to his spinal column and partial paralysis of the left leg. They could however, find no evidence of any bony lesion. They declared the disability to be functional rather than organic. The medical witnesses acquitted Sykes of malingering and testified that he was partially disabled but that he would eventually recover. The industrial board concluded that while Sykes was suffering from a partial disability at the time of the hearing, the disability would end on or about May 1, 1931 and ordered the payment of compensation until that time. Sykes then appealed to the district court, Musselshell county, Montana where the case came to trial, apparently, after May 1, 1931, the date set by the industrial commission for the termination of Sykes' disability. In the district court, lay witnesses testified that Sykes was then unable to perform any labor that he became exhausted driving a car, and that he was in no better condition than at the time of the hearing before the board. The physicians who testified at the board hearing had re-examined Sykes and testified in the district court that Sykes' condition was due to traumatic neurosis and that it was uncertain how much of the condition was due to physical causes and how much attributable to psychic and mental causes. The district court concluded that the industrial board erred in finding that Sykes' disability would end May 1 and thereupon awarded compensation for partial dis-

ability permanent in character. The employer appealed to the Supreme Court of Montana.

The neurotic condition incapacitating Sykes, if solely the result of an industrial accident, entitles him to compensation, said the Supreme Court. The fact that he, but for the want of sufficient will power, could throw off his condition, brought about by hysteria and neurosis caused by the injury, cannot deprive him of compensation based on his inability to work. If the disability could be overcome by a simple operation, or by definite treatment, and continues only because the injured workman refuses to submit thereto, no compensation would be allowable. The foregoing rule is not applicable to the present case, however, said the court. The evidence shows that the recovery of Sykes is highly problematic, being dependent on a change of mental condition to be brought about through the operation of some stimulus impossible of accurate application and dependent solely on chance and the efforts of the workman. Furthermore, the court said, the evidence gives no assurance that Sykes though he exercises his mental processes to the utmost could by the exertion of will power "snap out of it." Under a liberal conception of the workmen's compensation act, concluded the court, if it is shown that an injured workman will suffer disability for an indefinite period his disability is permanent in character. The district court, therefore, did not err in awarding Sykes compensation for a partial disability permanent in character—*Sykes v Republic Coal Co (Mont)*, 22 P (2d) 157.

Malpractice **Jury May Not Disregard Expert Testimony**—The plaintiff sued the defendant-physician for alleged malpractice in treating a complicated Pott's fracture. At the trial the plaintiff called a physician who, on cross examination, testified that under the circumstances the result obtained by the defendant was excellent and that there was nothing to criticize in the defendant's treatment of the case. There was no other medical testimony introduced. Nevertheless the jury returned a verdict for the patient and the physician appealed to the Supreme Judicial Court of Maine. It is difficult to understand why said the Supreme Judicial Court, in view of the only expert testimony adduced at the trial, the case should have been submitted to the jury. True, the expert witness had been summoned by the plaintiff and the important features of his evidence were in answer to questions propounded by the attorney for the defense, but neither his professional knowledge nor his integrity was attacked. The expert witness was apparently frank unprejudiced unbiased and fair in all of his statements. His testimony stood uncontradicted. The verdict assumed it to be of no value whatever. The jury was not justified in disregarding it. The judgment in favor of the patient was accordingly reversed—*Burns v Haskell (Maine)*, 166 A 384.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

- Contribution to Problem of Enzyme Action in Mechanism of Cataract. A. Saueremann. New York.—p. 985.

Use of Calcium Gluconate in Eye Diseases.—Theobald gives the results in twenty-four cases of inflammatory ocular disease in which calcium gluconate was used. She observed that pain ceased usually two hours after the first injection after the second injection in severe cases there was a definite rapidity of absorption of exudates, breaking down of adhesions and dilatation of the pupil, the improvement in the general health was definite and the patients gained in weight and acquired a feeling of well being. It was necessary to remove as thoroughly as possible all foci of infection. When this was not done, after the first general improvement progress was retarded or there would be recurrent attacks, which required more frequent doses of calcium and finally the removal of these foci. The course of the recurrent corneal ulcers was shortened with calcium therapy.

Phrenicectomy. Use of Short Incision.—Delaney states that it is possible to avulse the phrenic nerve through an incision one-half inch long. Never should it be necessary to extend the incision to more than seven-eighths inch. He presents a technic in which phrenicectomy is performed through an incision of minimal length. After the administration of a capsule of sodium amylal two hours preceding the operation, and of a hypodermic of one-sixth grain (0.01 Gm.) of morphine sulphate and $\frac{1}{150}$ grain (0.0004 Gm.) of atropine sulphate before being sent to the operating room, the patient is placed on the table reclining at an angle of about 30 degrees. The face is turned away from the operator, who stands on the affected side. After the skin is prepared, the patient is asked to begin to raise the head with the face remaining turned away. The border of the clavicular insertion of the sternocleidomastoid muscle can be easily palpated and the incision is to be made along the lateral border of this portion of the muscle. A 1 per cent solution of procaine hydrochloride is infiltrated in the skin, beginning at a point one fingerbreadth above the clavicle. The infiltration may continue for about an inch upward, following the border of the clavicular insertion of the sternocleidomastoid muscle. An incision one-half inch (1.25 cm.) long is then made. The tissues are separated by blunt dissection with two plain thumb forceps. The platysma muscle is separated in the direction of its fibers. The cervical fascia is opened. Dissection is toward the anterior scalenus muscle. After the fascia has been penetrated retractors are used. The dissection continues down on a pad of fat. It is essential to dissect through this pad of supraclavicular fat in order to come directly down on the anterior scalenus muscle in the normal location of the phrenic nerve. The phrenic nerve is grasped gently with the thumb forceps. The nerve is freed from the surrounding areolar tissue and infiltrated high up with a 1 per cent solution of procaine. The nerve is then clamped with an avulsor the shank of which has been passed through the finger loop of an ordinary hemostat. The latter serves as a fulcrum as the avulsor is being rotated. The nerve is cut with scissors as high above the avulsor as possible and then slowly twisted on the shank of the avulsor as the handle is rotated. The baffle at the distal end prevents the nerve from slipping off the instrument. Attachments of fascia to the nerve should be freed from the nerve with a tissue forceps as the avulsion progresses. After a few inches has been removed there is a characteristic snap and the nerve can be lifted out of the incision. There should be no hemorrhage after the removal of the nerve. The tissues are sponged and if dry they are closed. A few interrupted sutures of number 0 plain catgut close the fascia and the platysma muscle. The skin may be closed with one skin clip, which is removed on the third day.

Combined Phrenic Exeresis and Scalenotomy.—Aycock describes an operative method a combined phrenic exeresis and scalenotomy in which the level of the incision is determined by placing the fore and middle fingers just above the upper border of the clavicle. At this junction the scalenus anterior

muscle is palpated and at this level from 4 to 5 cc of 0.5 per cent solution of procaine hydrochloride is injected in the cutaneous and subcutaneous tissue. The line of incision extends from a point about one-fourth inch in front of the dorsal border of the sternomastoid muscle to a point just in front of the ventral border of the trapezius muscle, approximately $1\frac{1}{2}$ inches in length. The knife is used only through the skin, superficial fascia and platysma muscle and then dissecting scissors are used to uncover the ventral surface of the anterior scalenus muscle. Small blunt hook retractors are inserted and retracted in the line of incision. Once the muscle has been uncovered the phrenic nerve is located, injected with procaine lifted out of its bed dissected free, cut and slowly avulsed. Subsequent to the avulsion, the scalenus anterior muscle is dissected free and a small periosteal elevator passed behind it leaving the fifth, sixth and seventh cervical nerve trunks uninjured. All the fibers of this muscle are severed in this way except a few that come off from the transverse process of the sixth cervical vertebra. These fibers are picked up with rat tooth forceps and teased apart with scissors. The fifth cervical nerve trunk is gently retracted downward and toward the midline. The scalenus medius and posterior are picked up and either cut or teased apart with blunt pointed scissors. The fibers originating from the transverse process of the seventh cervical vertebra must be severed. There is usually no bleeding except slight oozing from the severed muscle fibers. The author points out that the results in his seventy cases indicate that this combined operation has had a distinct advantage over phrenic exeresis alone.

New Method of Repair for Femoral Hernia—Cooper nail uses the same technic for simple and strangulated hernias except in the manner of dealing with the intestine and in the selection of the anesthetic. His procedure is as follows. An incision is made through the skin from 10 to 12 cm long parallel with and about 3 cm above Poupart's ligament. After the fascia is exposed the lower flap of the skin is dissected downward until the hernial sac is completely isolated. The sac is opened, if it contains adherent omentum, this is separated and reduced. If the sac contains intestine and the constriction is tight enough to prevent easy reduction no attempt is made to reduce it until the constricting band is cut later on. The upper flap is retracted and an incision is made through the aponeurosis of the external oblique parallel to Poupart's ligament from 2 to 3 cm above the inguinal canal. An opening is made through the internal oblique and transversalis muscles in a line parallel with that of their fibers. After the peritoneum is exposed and an incision from 4 to 6 cm long is made in it, a finger is hooked under the strangulated intestine. If gentle traction combined with slight pressure from below does not release the intestine, the constriction is cut from below. After the constriction is released and the strangulation relieved, the injured intestine is lifted out of the abdominal cavity along with as much of the healthy intestine as is necessary if resection is to be performed. If a resection is necessary, there is no danger of injury to the anastomosis as there is in reducing it in the low operation. The hernial sac is freed completely in the canal so that it can be inverted into the abdominal cavity. The sac is picked up with the forceps and pulled up through the abdominal incision, and the peritoneum is sutured all around it, closing the abdominal cavity. The sac is then amputated flush with the fascia. It may be necessary to ligate one or two small vessels in the sac. The separated muscles are sutured together, the sutures passing through both walls of the sac, over this the fascia is then sutured with interrupted chromic catgut sutures with an occasional deep suture passing through the stump of the sac. The skin is closed in the usual manner without drainage unless there is an excess of adipose tissue or any danger of infection.

Treatment of Upward Dislocation of the Acromial End of the Clavicle—Copher points out that the rational position for fixation of the shoulder after reduction of an upward dislocation of the outer end of the clavicle is backward and upward. This position is accomplished by the use of an elastic bandage placed about the shoulders in a figure of eight. Before the elastic bandage is applied a pad of cotton and saddle felt 1 or 2 inches thick and about 2 inches in diameter is

placed over the outer end of the dislocated clavicle and held in place by adhesive plaster. The axillary folds and spaces are padded with cotton for comfort and to absorb perspiration. The elastic bandage is applied about the shoulders in the manner of a figure of eight, making pressure on the pad overlying the outer end of the dislocated clavicle. It is desirable to use a bandage containing rubber. The elastic bandage pulls the scapulas and at the same time effectively depresses the pad and the dislocated end of the clavicle. The bandage is prevented from slipping by the insertion of safety pins at points where the bandage crosses. The tension of the elastic bandage is made more effective by placing the forearm on the injured side in a fairly tight sling. The sling displaces the weight of the extremity from the shoulder to about the neck and helps to elevate the shoulder above its normal level. An axillary pad is used to prevent inward displacement of the shoulder.

Diagnosis of Carotid Body Tumor—The present criteria of the Greenes in arriving at a diagnosis of tumor of the carotid body are (1) the position of the tumor (2) its movement laterally but absent vertical mobility, and (3) its transmitted but nonexpansile pulsation. Because of the proximity and frequent attachment to the underlying great vessels of the neck, branchiogenic cysts may fulfil all these criteria. Heretofore the diagnosis of a tumor of the carotid body as well as branchiogenic cysts has been made with difficulty, and most frequently the true condition was not established until the neck had been opened when the exact nature of the lesion became apparent. The ability to make a correct preoperative diagnosis is of utmost importance because of the inequality in the surgical difficulties encountered in the two lesions: the branchiogenic cysts are usually relatively simple, while a tumor of the carotid body requires skilled surgical ability. The mortality and morbidity in the two conditions vary: the former is practically nil, while the latter is extremely high. The history and physical observations in the two conditions may be insufficient to determine the exact status of the lesion. The introduction of an 18 gauge needle will help greatly in arriving at the proper diagnosis. By this means the contents may be aspirated, if the tumor is cystic and by demonstrating the presence of cholesterol crystals a diagnosis of branchial cyst is established. Should the diagnosis still be in doubt, an opaque medium may be introduced through the needle and a roentgenogram taken which will be of further aid. If the tumor is discovered to be solid a syringe may be attached to the needle and some of the material aspirated and immediately examined, thus establishing its specific identity. Should the lesion be an aneurysm or should the needle enter any of the large vessels no damage can result.

Function of Reattached Retina—Kronfeld states that, in partial or complete macular detachments of a duration of less than two months and also in partial macular detachment of more than two months the prognosis concerning restoration of function is favorable. He studied the function of the reattached retina in six cases of partial sector-shaped retinal detachment of more than one month which yielded to Gonn Lindner or Weve diathermic operations. The 2 degree white isopter was normal outside its limitation at the area of opera-

tion The 0.17 degree white isopter was found constricted in each case the degree of radial constriction apparently strictly depending on the duration of the detachment and perhaps on the age of the patient The dark field paralleled the isopter for 0.17 degree closely, outside of the fact that in one case of long standing the dark field (taken with the usual target) remained at zero over the entire reattached area The longitudinal extent of the constriction for white colored and light targets in the dark room paralleled the extent of the detachment No definite signs of remote, permanent noxious effect from uncomplicated operations after Gonn Lindner Lindner-Guist and Weve Safar were found

Use of Nupercaine in Ophthalmology—Dillon and Greer used nupercaine in ten cases of pterygium by instillation and injection None of the patients complained of severe after-pain, and in a number there was no postoperative discomfort whatever With nupercaine a somewhat longer time is necessary for the induction of anesthesia, from fifteen to twenty minutes in cases of pterygium In some cases sufficient anesthesia could be obtained by instillation alone while in others the injection of from 2 to 3 drops of a 1:1,000 dilution was necessary The freedom from after-pain was quite definite as compared with that in patients operated on under cocaine anesthesia A 1:500 ointment of nupercaine was used and freedom from after pain was noted in cases of corneal abrasions pterygium and other conditions Particularly because of its prolonged anesthetic effect nupercaine is a valuable drug in certain ophthalmologic procedures

Sedimentation Test in Rheumatoid Arthritis—The results of Stansby and Nicholls investigation of 597 cases indicate that the corrected sedimentation index (Rourke and Ernste) is a reliable criterion of the activity or severity of the arthritic process at the time of testing and that any fundamental change in the clinical condition produces an immediate corresponding change in the sedimentation rate Patients with a greater degree of involvement of the joint and a longer duration of the disease have higher sedimentation rates than those with less involvement of the joint and shorter duration of the disease Considerable variation occurs, however, in individual cases The phenomenon that the average sedimentation rate progressively increases with advancing age appears to be due primarily to the increasing accumulation of patients having severe arthritis in whom the disease began at some earlier age From a study of seasonal variations in the sedimentation rate over a long period it was deduced that the rate was higher in winter than in summer, while spring and autumn occupied intermediate positions No relationship was found between the sedimentation rate and the streptococcus agglutination reaction The sedimentation test is a reliable measuring rod of the activity or severity of the arthritic process By repeating this test at regular intervals, the progress of the patient may be determined The sedimentation test provides a ready aid for correctly estimating the value of the treatment instituted

Oxygenation of Concentrated Versus Normal Bloods—The studies of Ray and his associates of the dissociation curves of normal and artificial polycythemic bloods show no difference in the tension of oxygen required to produce a given saturation When these types of blood are oxygenated by the perfused lung, the normal blood becomes completely oxygenated while the concentrated blood is never fully saturated Increasing the oxygen tension increases the saturation of the concentrated blood The authors ascribe the difference between the two bloods to the greater rate at which hemoglobin in the polycythemic blood passes through the lungs coupled with a delayed diffusion resulting from capillary dilatation

Immunity in Diabetes—Richardson states that complement in the blood of diabetic patients does not differ in amount

from that in the blood of nondiabetic patients. This is true whether or not infection is present. The antibacterial power of the blood of diabetic patients as measured by standard methods tends to be less than that of nondiabetic. Diabetic patients are less able than nondiabetic controls to form agglutinins following their inoculation with typhoid vaccine. From these studies the author concludes that any deficiency in the antibacterial reactions of the blood of the diabetic patient comes rather from impairment of the amboceptor than from any lack of the amount or the activity of the complement. This is true of both the natural amboceptor as shown by the bactericidal test and of the acquired amboceptor as shown by the formation of agglutinins.

Schwartzman Phenomenon Heretofore Undemonstrated Antitoxins in Man.—Klein presents evidence that, in patients recovering from systemic gonococcal infections and from typhoid specific antitoxins developed spontaneously, as demonstrated by the Schwartzman phenomenon. It appeared highly suggestive that in these patients recovery was related to antitoxin formation. Serum of certain patients with previous meningococcal infections and of certain controls was shown to possess meningococcus antitoxin. This was group specific. The capacity of antigenococcus serum to neutralize meningococcus reacting factors and of antimeningococcus serum to

neutralize gonococcus reacting factors is further evidence of the biologic relationship between the gonococcus and the meningococcus. The author is extending these investigations to other diseases caused by bacteria possessing toxins potent in eliciting the Schwartzman phenomenon. His aim is to study whether spontaneous formation of antitoxin takes place. If further studies are fruitful, attempts should be made to confer immunity against this entire group of diseases, actively by prophylactic injections of toxoid and passively by the administration of immune serum to actively ill patients.

Prophylaxis Against Tetanus.—The experiments of Bergey and Etris on guinea-pigs with tetanus toxoid showed that three doses of 1 cc each bring about a high degree of protection. From the results obtained in guinea pigs, it is believed that human beings may also be protected against tetanus by the administration of several doses of toxoid. This method of protection obviates the hypersensitization against horse serum that may occur from passive immunization with tetanus antitoxin.

Normal Flora of the Prepuberal Vagina.—Pettit and Hitchcock made six cultural examinations of the vaginal flora of forty-six children between the ages of 14 months and 11 years. The majority of these cultures were obtained with sterile cotton tipped applicators. The swab was rolled gently on a portion of a 5 per cent rabbit blood infusion agar plate of pH 7.4 after this a smear was made on a clean glass slide. The plates were at room temperature for from fifteen to twenty minutes until they could reach the laboratory incubator. Sterile glass spreaders were used to distribute the organisms over the surface of the agar. Incubation was at 37.5 C. Smears were stained by Gram's method. The authors' studies show that the flora is predominantly diphtheroid in character. Gram-positive cocci, such as nonhemolytic streptococci and non-pigment-forming staphylococci, are present less frequently and in smaller numbers. Organisms of the intestinal flora seldom if ever occur in healthy children though in severely ill patients there is a distinct tendency for them, together with *Streptococcus aureus*, to overgrow the normally occurring flora.

Sympathectomy in Anterior Poliomyelitis—The result in Telford and Stopford's three experimental cases of total paralysis of one or both lower extremities shows that sympathectomy has been of great benefit to the patients. During the whole winter their limbs have remained warm and there have been no distressing chilblains or a period of incapacity for school or work. They are most enthusiastic about their greatly increased comfort and happiness, even in the coldest weather, the warmth is most striking and in a paralyzed limb seems quite unnatural. The color has improved in all, but when the patient has been standing for a time there is still a trace of cyanosis, mostly in the calf, showing that in the erect position there is still some lag in the venous return. Although the number of cases is small and but one winter has passed since the operation, the authors think it likely that sympathectomy will prove of real value in patients who have had anterior poliomyelitis and who are subject to recurrent chilblains and ulceration. They maintain that if ganglionectomy is adequately done there is no question that the result is complete and permanent. By now there is ample support for this contention in the literature of ganglionectomy in both man and animals.

Thoracic Ganglionectomy in Parkinson's Syndrome—Harrower and Ghosh removed the first thoracic ganglion in two cases of Parkinson's syndrome. The operation effected an improvement much more marked in the woman than in the man, but neither subject was improved to such an extent as to become a useful member of the community. The condition in the woman was not of long duration. She was improved to such an extent that she was able to attend to her own wants. The results point to the fact that the heart is intrinsically controlled. In the past, the sympathetic system has been blamed for all sorts of ills, but, judging from the results of sympathectomies in various parts of the body, the action of the sympathetic system is a subsidiary one in the normal human economy. When the sympathetic nerve is causing spasm in

disease conditions, as in carcinoma of the bladder or Raynaud's disease, section of the nerves involved has a beneficial result, but in the normal economy the sympathetic nerves, like the appendix or gallbladder, can be dispensed with.

- *Vitamin A and Infection. Review of Recent Work. F W Fox—p 190
Observation on Mosquito Breeding in Pawpaw Trees. J E Mountjoy—p 214

Vitamin A and Infection—Fox states that an animal's resistance to infection depends among other things on an adequate supply of vitamins in the diet. While other vitamins take some share in maintaining this resistance, the part played by vitamin A is unquestionably of greatest importance, it is best regarded not so much as a positive anti-infective agent, indiscriminate in its action, but rather as a constituent in the diet a deficiency of which leads to increased susceptibility to infection. Regarding the important practical question as to the amount of the vitamin that is required, it would appear that 1 The rarity with which the more characteristic signs of vitamin A deficiency, such as xerophthalmia and night blindness, are encountered among civilized races suggests that the minimal requirements are probably small. 2 There is no doubt that people in different parts of the world are living on diets which are dangerously near and sometimes temporarily below this minimal requirement. 3 The body possesses considerable powers of storing this vitamin and hence the person can if necessary be comparatively independent of the immediate supply in the food. On the other hand, allowance should be made for the fact that in some persons this absorbing or storing capacity is curiously defective. 4 Whether the diet often falls short of the optimal requirement for the maintenance of full health and vigor is at present a debatable question. The fact that the more generally recognized symptoms disappear so rapidly when treated with small amounts of the vitamin, together with a certain amount of direct evidence that the use of large amounts does not lead to the development of unusual resistance to the common infections, makes it probable that no more of this substance is required than is provided by a well chosen diet containing a moderate amount of fresh food. 5 Such evidence as is at present available indicates that no dramatic demands are made on the vitamin reserves during the course of infectious disease, but the possible value of vitamin A therapy calls for the fullest investigation. The manner in which vitamin A influences resistance to infection is but little understood.

Diagnostic Lumbar Puncture in Intracranial Hypertension—Schaller presents clinical and experimental evidence to support the contention that there is no proof of sudden wedging or movement of the contents of the posterior fossa into the foramen magnum following spinal tap in open craniospinal pathways, even in the presence of increased intracranial pressure. There is, however, reason to believe that so-called herniation is an expression of general brain swelling and edema and may be due to changes in intracranial pressure and vasomotor paralysis and shock from various causes. Sudden and excessive withdrawal of fluid by spinal tap may produce such edema, as well as similar withdrawal of fluid from other parts of the cerebrospinal fluid system. Of the four deaths in the

series, two can be excluded as due to properly performed diagnostic punctures, two may or may not have been determined by diagnostic punctures. The incidence of postpuncture accidents is greater in supratentorial than infratentorial tumors, and the incidence of sudden death is greatest in vascular lesions. The author admits that even a properly performed lumbar puncture may in exceptional cases hasten the course of a prognostically serious and often hopeless pathologic condition found in intracranial hypertension, but this is not a just criterion by which to designate the procedure as unsafe, rather the accumulated experience of late years would justify the opinion that when properly done the procedure is reasonably safe because of the low mortality—only two reported cases (Putnam) in recent years—and justifiably indicated because of the valuable diagnostic information it affords.

Dietetic Therapy of Gallstone Disease—Saiki produced calculi in the bile duct, the kidney and the urinary bladder of animals fed a deficient vitamin D diet. He corroborates this fact clinically by presenting a case of late rickets complicated with gallstone. The patient received a diet deficient in vitamin D. The gallstone was experimentally dissolved *in vivo* by adding an adequate amount of vitamin D to the diet. Thus it was shown definitely that vitamin D is the most important nutritive element which is kept in closest connection with the therapy and the prevention of gallstones.

Flocculation Test with Antigen for Diagnosis of Syphilis—Michailoff used white mastic and an antigen similar to that of Bordet-Ruefens with the incorporation of brain of a guinea-pig. His antigen is prepared in the following manner. One hundred Gm of heart of calf, well cleaned and chopped is fixed in 125 cc of a 95 per cent solution of alcohol for from twelve to fourteen hours. After filtration the alcohol is replaced by 200 cc of pure acetone. To this mixture, 2 Gm of small cut pieces of the brain of a guinea-pig is added. This is kept for six hours at ordinary room temperature, and the acetone removed by filtration is replaced. Four hours later another filtration is done, the acetone is left to evaporate at the temperature of the laboratory and the filtrate is weighed. To each gram of tissue, 2 cc of a 95 per cent solution of alcohol is added and the extraction is continued for ten days. After filtration, an amber-yellow liquid, the antigen, is obtained which can be preserved for years. The alcoholic solution of mastic is prepared by dissolving 1 Gm of mastic in 10 cc of absolute alcohol. This is filtrated after twenty-four hours. Of this solution, 1 cc is added to 10 cc of antigen. Usually, the antigen is diluted 1:20 with 85 per cent solution of sodium chloride of which dilution 0.25 cc is employed for the reaction. The author's flocculation test requires two test tubes and if the complement and the antigen are well titrated and the serum inactivated the test is performed in fifteen minutes. The first test tube contains 0.25 cc of antigen, 0.1 cc of inactivated serum, 2 units of complement and the necessary amount of physiologic solution of sodium chloride to bring up the volume

of mixture to 0.75 cc. In the second or control tube are placed the same ingredients with the exception of antigen. These two test tubes are gently shaken for four minutes while the formation of air bubbles is avoided. Shaking the tubes less or more time will produce a false positive reaction or an incomplete fixation of complement. By leaving the tubes at rest for twenty-four hours, gross flocculation is shown in positive serums. Hemolysis is obtained more rapidly than in the Bordet-Wassermann test and the results are more distinct and more visible. The slightly anticomplementophil serums do not impede the reaction. The strongly anticomplementophil serums can be tested by using four or six test tubes with increasing amounts of complement. The author made 2000 tests based on this simple method and compares its results with those obtained by the Bordet-Wassermann reaction and Kahn's test. In comparing the results obtained by his test, the author claims that it did not show a single case of false positive reaction and that it perhaps failed in three cases in which the Kahn test failed also, while the Kahn test showed in eight cases and the Bordet-Wassermann in sixteen cases a false positive reaction. On the other hand, the Kahn test failed in nine cases, was weaker than the author's test in thirty-five and was stronger in twenty-one. The Bordet-Wassermann reaction failed in fifty-seven cases and was weaker in eighty-two when compared with the Kahn and the author's tests. Furthermore, during the author's investigations it appeared clear that his as well as the Kahn test is positive earlier than the Bordet-Wassermann reaction, and that they become negative much later in the cases treated.

- *Flexion Contraction of Elbow as Sign of Meningeal Inflammation R. Almansì—p. 2003
- Leukemic Lymphadenosis Case G. Fabri—p. 2006

Elbow Contraction as Sign of Meningeal Inflammation—Almansì experimented with the following technic on thirty-seven patients suffering from tuberculous, cerebrospinal, epidemic syphilitic and protitic meningitis and meningism. The patient is placed in dorsal decubitus, the arm extended backward and as high as possible. The patient's wrist and elbow are supported by an assistant while the author, standing on the other side, bends the patient's neck forward and a little to the opposite side and fixes the thorax. Afterward the positions are inverted and the other arm is examined. If the result is positive there is a flexion of the forearm corresponding usually in intensity to the other signs of contraction. By analogy to the denomination used by Kernig, the author calls this sign "flexion contraction of the elbow." Patients recovering from cerebrospinal meningitis when subjected to this technic evince a pain localized along the median nerve, evidence of a neuritis which otherwise cannot be revealed. In five cases the reaction was negative whereas in all other cases there was a unilateral or a bilateral positive reaction. Comparison with the Kernig and Brudzinski signs shows that elbow contraction may be missing when the former are present, that it may be present when they are missing, or that both may be found in varying intensity. Comparisons made with Brudzinski's and Northrup's sign on the upper extremities clearly demonstrate a greater incidence of elbow contraction. The author obtained a positive response in infants from 2 to 4 months of age, this is significant in consideration of how little value is attributed to signs of hypertonia in early infancy. In opposition to Kernig's sign, elbow contraction is more frequently present in tuberculous meningitis forms than in epidemic cerebrospinal forms. Elbow contraction is generally missing in paretic extremities, its absence however, does not necessarily imply paresis of the limb. Elbow contraction was found in one case of generalized arteriosclerosis of the small cerebral arteries. Unilateral elbow contraction was encountered in eleven cases. The Kernig and Brudzinski signs are found unilaterally in cases of localized lesions of the brain. The author maintains that flexion contraction does not have a pathogenesis different from that which conditions the Brudzinski and Kernig signs. Brudzinski explains the pathogenesis of his sign by referring it to

hypertonia or the spastic state. The origin of this hypertonia has not yet been determined, although it seems to be radicular. The author maintains that his sign is a uniregional or multi-regional contraction that involves the physiologically predominating muscular groups.

*Curable Cutaneous Induration of the New Born Case C P Montagna—p 415
Gastroscopy J Piñero Sorondo—p 418

Curable Cutaneous Induration of the New-Born—Montagna says that curable cutaneous induration of the new-born is a syndrome that generally appears in children who, having been born suffering from blue asphyxia, are submitted to various maneuvers that they may be reanimated. Labor in these cases is difficult and prolonged, and sometimes the application of forceps or the performance of a cesarean section is necessary to end it. The three principal etiologic factors of the condition are the predisposing causes (constitution of the fat, endocrine and humoral disturbances and principally hypercholesterolemia), the obstetric trauma and the drop of temperature of the infant caused by the reanimating maneuvers. The pathogenesis is still unknown. It is believed that there is necrosis of the subcutaneous fat. Prognosis is good. The condition follows a benign evolution to spontaneous recovery. Massages, frictions and unctions should be avoided. The author reports the case of an infant who was observed from 1 to 5 months of age. From the type of the lesions, the etiology (the child had been born in blue asphyxia and had been submitted to reanimating maneuvers) and the evolution of the condition to spontaneous recovery, the author concludes that his case was a typical case of syndrome of curable cutaneous induration.

Primary Sarcoma of Stomach W Schultz—p 947

Results After Cholecystostomy—Dieterich reviews 384 clinical cases of cholecystostomy performed from 1900 to 1931 at the surgical clinic of the University of Giessen. In typical cholecystostomy, the gallbladder was exposed, opened at the neck, cleansed, drained and packed. Atypical cholecystostomy was chiefly used in pericholecystic abscesses. Cholecystostomy was the operation of choice in 128 cases of cholelithiasis and acute cholecystitis, in 115 cases of acute and chronic empyema of the gallbladder and in 29 cases of pericholecystic abscess. The atrophied gallbladder constituted the indication for operation thirty times, catarrhal cholecystitis twenty five times, carcinoma of the gallbladder twenty-two times, and dropsy eighteen times. Of the 384 patients 33 died immediately after the operation, 5 shortly after owing to cholecystitis with stones, 8 owing to carcinoma and 4 owing to pancreatic necrosis. In forty-five other cases the primary disease was responsible for death rather than the cholecystostomy. Few complications worthy of note were observed after operation. In only 8 of the 384 cases did the fistula fail to close spontaneously, necessitating secondary cholecystectomy. Consequently, this slight incidence cannot be regarded as a contraindication for cholecystostomy. In 334 cholecystostomies there were 45 postoperative recurrences of which 35 necessitated cholecystectomy, 8 cholecystectomy together with choledochotomy and 1 choledochotomy. Thus the gallbladder rather than the common bile duct was the seat of the disease. Only two cases out of thirty-one showed any recurrence of gallstones, in general, stones seldom recur after cholecystostomy. When the bladder was being drained of stones in atypical cholecystostomy, some were left behind because of complications preventing their recognition. The author concludes that cholecystostomy shows satisfactory results in carefully selected cases. This operation is

justified when cholecystectomy, which is always more desirable, offers technical difficulties or when the general condition of the patient necessitates rapid termination of the operation. In the latter event, empyema of the gallbladder with and without complications in advanced age would be the main indication. With its inherent defects, cholecystostomy will always be only a makeshift, which should not, however, be completely rejected.

*Clinical Aspects and Pathologic Histology of Endocrine Glands in Scleroderma J Follmann and B Ballo—p 1779
Quantitative Turbidity Reaction as Indicator of Value of Therapy of Syphilis C Stern—p 1788
*Liver Therapy of Psoriasis T Gruneberg—p 1793

Scleroderma—Follmann and Ballo give detailed clinical histories of two patients with scleroderma and review 200 cases from the literature. This review shows that scleroderma may develop in patients of every age. The aspects of the disease vary so greatly that a uniform etiology is hardly possible, but it is worthy of note that in 32 per cent of the cases the anamnesis reveals vasolability of the extremities, acro-asphyxia and cold as promoting factors (Raynaud's syndrome). Exposure to cold is often a causal factor of scleroderma, but the influence of heat also may be a cause, although it is extremely rare. Injuries of the thighs, multiple fractures, and traumas of the jaws likewise have been followed by scleroderma. In some instances the scleroderma seems to follow the course of the nerves. Functional changes in the sympathetic nervous system and consequent functional disturbances in the endocrine system have often been considered pathogenic factors. But the observations are not uniform, for hyperfunction as well as hypofunction of the thyroid, hypofunction of the hypophysis, suprarenals and ovaries and pluri-glandular insufficiencies have been observed. Moreover, cases in which endocrine disorders are absent are just as frequent as those in which they are present. The studies on the nervous system give no definite information, for the sympathetic as well as the parasympathetic may show an increased irritability. A review of the therapeutic aspects reveals improvement after various treatments, but most frequently after organotherapy, particularly with thyroid extract. Another factor that makes the estimation of scleroderma difficult is that it passes through several stages. On the basis of a consideration of the entire course of the disorder, the authors conclude that the disorder begins always as a disturbance of the skin, independent of a disease of the internal organs, although a predisposition may exist. The loss of the elasticity of the connective tissue and of its adaptability to the functional requirements explains impairment of the circulation not only as the result of the lack of elasticity of the skin but also because of pressure. The organism makes efforts to compensate for this but since impairment of the circulation also affects the vasomotor nerves, it becomes understandable why in the first stages of the disorder the sympathetic nervous system is in a state of hypersensitivity. A little later, when the nervous system is no longer able to control the function of the skin, the organism must exert the endocrine system because it dominates the sympathetic. On this basis it must be assumed that during these beginning stages the nervous and endocrine systems still may exert an influence on the process, but after that an improvement can hardly be expected. In resorting to endocrine therapy the local measures should not be neglected, and eventually parenteral protein therapy may be tried.

Liver Therapy of Psoriasis—Reports about favorable effects of liver therapy in psoriasis induced Gruneberg to try this treatment. Injections of liver extract were given every second day, and the patients took liver by mouth in the form either of fresh liver or of liver extract. In psoriatic patients, liver therapy decreases the tendency to relapse, but it also influences the existing cutaneous manifestations. It seems that the therapeutic effect is better if the patient is exposed to the influence of light, but the exposure should not be too severe. In order to compensate for the deficiency of sunlight in the big city, particularly during the winter months, the patients were given quartz lamp irradiations, but the doses were smaller than is usually the case so as to avoid irritation. In spite of the fact that the liver therapy occasionally produces surpris-

ingly good results, the author admits that aside from a reduction in the tendency to relapse, it accomplishes, on the whole, no more than the customary treatments, for liver therapy may fail as well as the other treatments, and as a rule it does not make the application of ointments unnecessary. The mechanism of liver action, which may involve several components, is not yet clear, but it is possible that an increase in the sulphur or glutathione content of the skin is an essential factor.

 Vomiting of Pregnancy and Its Treatment E Schwab—p 1897

Postoperative Incisional Hernias—Florcken and Kobel report observations in 158 cases of incisional hernias, of which 96 could be reexamined. They show that, although the diagnosis is comparatively simple, erroneous diagnoses do occur. The presence in the scar of hard, pressure sensitive areas or of protrusions, caused by paralysis of portions of the abdominal muscles following cutting of motor nerves, may cause such mistaken diagnoses. The authors discuss the incidence of incisional hernias and state that in many of the cases observed by them drainage and packing had been necessary, while in others peritonitis or suppurations had existed. In only four cases was it certain that the operative wound had healed by first intention. Most incisional hernias develop during the first year after the operation. The authors consider operative repair indicated (1) in all small incisional hernias, because without operative intervention they have a tendency to become larger and the operation is usually quite simple, and (2) in the larger hernias that are accompanied by symptoms of incarceration and digestive and other disturbances. Operative treatment is contraindicated in unusually large hernias, in which closure of the defect is not likely. If the patient is obese, a reducing treatment may be instituted, for after that the repair of the hernia frequently becomes possible. Operative treatment is also inadvisable in patients with circulatory, respiratory or renal disturbances. In doubtful cases an electrocardiogram should be taken. Diabetes is a contraindication only when it is severe. Since complete relaxation of the abdominal walls is an essential requirement for the operative repair of incisional hernias, the authors consider spinal the most desirable form of anesthesia. They recommend as the best treatment the opening and removal of the hernial sac and the repair of the different layers of the abdominal walls. In suitable cases, free transplantation of the fascia may be resorted to, but the use of foreign bodies, such as silver wire netting, should be dispensed with as much as possible, because they readily lead to suppurations or the formation of fistulas. Later examinations on ninety-six patients revealed that fourteen had had a relapse. In nine of these the operation had caused an exacerbation, but the other five declared that they were free from difficulties and satisfied with the results of the treatment.

 Symptomatology of Recent and Habitual Adduction Supination Distortion of Foot E Delne—p 40
 *Occurrence of Tetanus After Timely Administration of Tetanus Antitoxin H Hanke—p 62

Cerebral Compression in Blunt Injuries of Head—According to Karitzky, compression of the brain in injuries of the head may be due to (1) a depressed fracture, (2) intracranial bleeding and (3) edema of the brain. A depressed fracture always produces a local pressure on the brain tissue and must therefore be treated by lifting the fragment. In the case of bleeding the local signs of compression are soon superseded by the signs of general compression of the brain. Every head injury should be examined roentgenologically to avoid

diagnostic errors. The subjective symptoms and clinical signs in concussion of the brain depend on the swelling of the brain resulting from trauma to the tissue of the brain. The author views the increase of pressure within the spinal canal as a functional compensatory phenomenon and does not favor interfering with it. Increase in the intracranial pressure is followed by increase in the intraspinal pressure. The latter has a tendency to lift the medulla from the bony base of the skull. The compression of the brain tissue against the unyielding dome of the skull is at first compensated by flattening out of the convolutions, later by diminution in the amount of the cerebrospinal fluid. For this reason spinal puncture is contraindicated in recent injuries to the brain. It is reserved for the treatment of late results of concussion in which there is no tendency to progression of the lesions. Subdural hemorrhage is treated by trephining and removal of the hematoma. The author's attitude toward the treatment of edema of the brain is conservative. He is not impressed with the results of osmotherapy as advocated by Weed and McKibben. Dehydration following the intravenous injection of hypertonic solution was demonstrated to be of short duration in experiments on animals, its effect not lasting over one hour. This is in part due to the fact that, after a certain amount of shrinkage of the brain volume through loss of water takes place, the sodium and chlorine ions of the hypertonic solution now lodged in the brain cells produce in their turn reabsorption of lost fluid. The treatment of prolapsed tissue of the brain is limited to prevention of further damage to it. With the disappearance of the general edema, the prolapse becomes automatically reduced.

Tetanus After Administration of Tetanus Antitoxin—Hanke reports two cases in which, in spite of proper treatment of the traumatic lesion and timely administration of a proper dose of tetanus antitoxin, tetanus developed in one patient on the eighth and in the other on the ninth day. The tetanus was severe and terminated fatally. Attention is called to Mosbacher's collected statistics in which 2,032 cases were reported in which tetanus developed in spite of the prophylactic injection of antitoxin. In only 745 of this number was the injection given during the first twelve hours. The mortality in the latter group was 209, or 28 per cent. The explanation is furnished by the observation of Delne and of F. Hamburger that the antitoxin content of the blood is suddenly diminished on the seventh or eighth day after its administration. If the wound is not healed by that time, reactivation of the infection may take place in the absence of sufficient antitoxin content in the blood to protect the organism. The author therefore recommends the second administration of a prophylactic dose of antitoxin on the sixth or seventh day. This is particularly indicated in cases in which the wound has failed to heal, as well as in cases in which bacteria persist in the depth of the wound. Compound, badly soiled fractures and wounds with deep pockets are particularly dangerous. The possibility of anaphylactic reaction must be kept in mind and met by proper measures, such as a change of serum, the use of a highly potent serum with small albumin content, and desensitizing methods.

Pathology of Traumatic Hemorrhages of Brain—Berner's forty-two cases of traumatic hemorrhages of the brain since 1930 consist of twenty-five with macroscopic hemorrhages in the fourth ventricle, four with hemorrhages in the central ganglions or immediate vicinity, nine with microscopic hemorrhages in the fourth ventricle and four without certain hemorrhages in the fourth ventricle (possibly because the direct cause of death was not the trauma of the head). He asserts that the place of predilection for traumatic hemorrhages at the base of the fourth ventricle is in front of the acoustic striae.

DEVELOPMENT OF KNOWLEDGE CONCERNING RÔLE OF SYPHILIS IN CARDIOVASCULAR DISEASE

LEWIS A CONNER, M.D.
NEW YORK

At the meeting of the American Medical Association last year the Frank Billings Lecture was devoted to a review of the important part played by the great physician whose name the lectureship bears in the astonishing progress made by medical education in this country during the past thirty years. The distinguished speaker, Dr Thayer, closed his remarks with the following prayer: "May he who has played so large a part in this progress long be spared to guide us with his wise counsel." This fervent wish, which surely must have been shared by everyone in the large audience, might well have been directed also to the lecturer himself.

It is sad indeed to realize that within a few months of the time these words were spoken both Frank Billings and William Sydney Thayer had ended their earthly careers.

In mourning the almost simultaneous loss of two such leaders one can be grateful for the knowledge that the inspiration derived from each will not soon be lost. The imprint of their personalities has been too deep to be easily effaced.

The importance of syphilis as an etiologic factor in cardiovascular disease does not at the present time, need to be labored. The disease is recognized universally, I think as being second in importance only to rheumatic fever and to senile degenerative changes in the arteries. Yet the general recognition of its importance is recent as compared with that of the other two factors mentioned. While the close relation of rheumatic fever to diseases of the heart was widely understood almost a century ago, the causal relationship between syphilis and disease of the aorta was still in dispute at the beginning of the present century.

Without attempting to decide whether or not syphilis was introduced into Europe from America at the time of the voyages of Columbus, the knowledge of that disease may be said to have begun with the devastating epidemic of syphilis which swept over Europe in the closing years of the fifteenth and the early years of the sixteenth century. This knowledge at first, as may be supposed, was chiefly confined to the external manifestations of the early stages of the disease, and even these were for many years hopelessly confused with those of other venereal and genito-urinary conditions. It is not surprising that the effects of syphilis on the

circulatory system, which for the most part become manifest years after the active and visible symptoms of the disease have subsided, should long have failed of recognition at a period when medicine as a whole was in so primitive a state.

As the disease came gradually to have more definite outlines, and especially as anatomic studies became more frequent, the association of a history, or of the external signs, of syphilis with aortic aneurysm began to be noticed.

Vesalius (1514-1564), who first called attention to aortic aneurysm, made no mention of its association with syphilis, but in the writings of two of his famous contemporaries, Pare and Fernel, are intimations that this association had been recognized. There was, however, in the minds of these, as well as of later, writers doubt as to whether syphilis itself or the accompanying mercurial cachexia was the actual cause of the trouble.

Osler,¹ in his Schorstein lecture, "Syphilis and Aneurysm," quoted the following lively passage from the English edition (1634) of Pare's works:

The aneurismaes which happen in the internall parts are incurable. Such as frequently happen to those who have often had the unction and sweat for the cure of the French disease, because the blood being so attenuated and heated therewith that it cannot be contained in the receptacles of the Artery, it distends it to that largeness as to hold a man's fist. Which I have observed in the dead body of a certain Taylor, who by an Aneurysma of the Arterious veine suddenly whilst hee was playing at Tennis fell downe dead, the vessell being broken his body being opened I found a great quantity of blood powred forth into the capacity of the chest, but the body of the Artery was dilated to that largeness I formerly mentioned, and the inner Coate thereof was bony. For which cause within a while after I shewed it to the great admiration of the beholders in the Physitions Schole whilst I publiquely dissected a body there, the whilst he lived said he felt a beating and a great heate over all his body by the force of the pulsation of all the Arteries, by occasion whereof he often swoounded.

It was, however, Lancisi² (1654-1720) who half a century later, by his anatomic studies, first supplied a more substantial foundation for the theory of this causal relationship. So strongly was he convinced of this association that in his posthumous work he discussed at length the subject of "aneurysma gallicum," or aneurysm due to the French disease (the common name for syphilis), and ventured to give the signs and symptoms by which it may be recognized.

Elsewhere, in his study of the causes of sudden death, he wrote:³

And indeed I cannot here conceal the fact, ascertained from frequent experience, that aneurysms destroy unexpectedly those patients particularly who lead a less continent and temperate

life Those indeed who live sparingly, with sobriety and contentment, are apt to be taken off with another type of disease, a slow and insidious dropsy, with lasting agony

The next important contributions to the subject of syphilis of the circulatory organs were those of Morgagni⁴ (1682-1771) These contributions were surprisingly numerous and striking

In his dissections of syphilitic bodies this author noted lesions in the heart, the pericardium, the aorta and other arteries In the case of a woman of 22 years who had shown grave symptoms of constitutional syphilis and of heart disease, autopsy showed extensive ulceration of the posterior surface of both ventricles In another case, that of a syphilitic man of 59 years who had died suddenly after a period of cerebral symptoms, the examination revealed rupture of a thoracic aneurysm as well as extensive disease of the arteries of the brain In the summary of this report Morgagni stated distinctly that the changes in the cerebral arteries and those in the aorta evidently had a common cause

As a result of Morgagni's important revelations concerning the effects of late syphilis on the heart and arteries, one might have anticipated thereafter a steady, progressive unfolding of knowledge concerning cardiovascular syphilis But there followed a long, sterile period during which even the evidence accumulated by Lancisi and Morgagni seemed to be entirely forgotten Proksch,⁵ in his "Geschichte der venerischen Krankheiten," sought the explanation for this strange phenomenon and placed the responsibility for it squarely on the head of John Hunter, the English surgeon, then at the zenith of his influence It was, he said, the few casual words uttered by Hunter that caused the subject of visceral syphilis to disappear almost completely from the textbooks on venereal diseases for more than half a century

Hunter stated⁶

We have not seen the brain affected, the heart, stomach liver, kidneys, nor other viscera, although such cases are described in authors

Elsewhere he wrote

The skin, throat and nose are more readily affected by the lues venerea than the bones and periosteum, which, on the other hand, suffer sooner than many other parts, particularly the vital parts, which perhaps are not at all susceptible of the disease

It was the weight of Hunter's great authority throughout the medical world that caused this error to have such direful consequences Proksch,⁵ who recognized the integrity and sincerity of Hunter, was disposed to lay much of the blame on his contemporaries and successors for their servile acceptance of these dicta "Blind trust in authority, indolence, ignorance of the literature and history submerged for a long time almost all real research and knowledge of the periods before Hunter"

It seems to be quite true that, from the middle of the second half of the eighteenth century to the beginning of the second half of the nineteenth, not only was little of importance added to the knowledge of the ravages of syphilis in the vascular system, but the

important contributions of Lancisi and Morgagni were allowed to pass into oblivion

It was during the early part of this period that Joseph Hodgson⁷ gave his classic description of "praeternatural dilatation" of the arch of the aorta (apart from aneurysm), in which he cited two typical examples with involvement of the sinuses of Valsalva and the aortic cusps and stated further that "aneurysm frequently exists at the same time" He credited Scarpa with having recognized this same condition of dilatation of the ascending aorta and with having found it frequently in association with aneurysm Hodgson wrote "The condition of the ascending aorta appears to be generally induced by a previous disease in the coats of the vessel, in consequence of which it loses its elasticity and does not again regain its natural dimensions after the blood has passed through it" But he failed to realize that the "previous disease" was syphilis, as did also apparently Scarpa,⁸ in spite of the fact that elsewhere he remarked "Syphilitic patients are very liable to steatomatous and ulcerative disease of the coats of the aorta"

So the matter rested at the end of the first half of the nineteenth century The hints of Pire and Ferri⁹ and the convincing anatomic demonstrations of Lancisi and Morgagni had disappeared from the writings on venereal diseases and had been forgotten Aneurysm was still common, but speculation as to its cause was concerned chiefly with a consideration of the importance of physical strain, either alone or in conjunction with the arterial changes common to later life Those who were tempted to accept the latter as a satisfactory explanation were constantly embarrassed by having it pointed out to them that the usual age for the appearance of aneurysm was a full score of years earlier than that for arteriosclerosis

The medical officers of the British army were much concerned over the high incidence of deaths from thoracic aneurysm among the soldiers and were seeking means to prevent them The reports of the army medical department for the decade beginning with 1860 contain a surprising number of studies and case reports of this condition In the report for 1862, Assistant Surgeon Lewes⁹ recorded a case from the army in India with the unequivocal title "Case of Aneurysm of the Thoracic Aorta Resulting from Secondary Syphilis" Osler, in his Schorstem lecture, in referring to the work of the medical officers of the British army said

Professor Aiken in the third edition of his textbook (1866) states that in 26 syphilitic soldiers who died during four years, 17 presented changes in the aorta, "cicatricial-like loss of substance of the inner coats, small local dilatations of the arteries, and in several cases aneurysmal expansions, one as large as an orange, which proved fatal"

The medical report for 1868 contains an interesting paper by Inspector General Lawson,¹⁰ dealing with the frequency of aneurysm among the British soldiers and its apparent increase Lawson disagreed with Rokitsky's view that aneurysm is due to atheroma and cited cases to show that aneurysm may be present in aortas which are free from atheromatous change He

expressed the belief that aneurysm often results from an acute ("phlegmonous") process in the wall, but he apparently did not suspect syphilis even though some of the patients cited were known to have had the disease.

The state of mind of the medical profession at this time toward the general subject of visceral syphilis is indicated by the opening paragraph of Wilks'¹¹ important contribution to that subject, which appeared in 1863.

The syphilitic affections of the internal organs of the body constitute a subject which is comparatively novel, and one, therefore, which is still open to further investigation. Although it is but a few years since specimens illustrating it were received with more than incredulity by the profession, yet so strong has been the evidence in favour of modern observations that few pathologists now retain any doubt about their general truth. Scepticism, however, does still largely prevail.

Wilks then described instances of syphilitic disease of the liver, spleen, larynx, trachea, lungs and other organs, referred to an aneurysm of the abdominal aorta found in a young syphilitic woman and described the case of a syphilitic woman of 38 years who died with severe cerebral symptoms and in whom necropsy showed softening in the right corpus striatum and thalamus.

The blood vessels of the brain were remarkably diseased, not by the usual atheromatous or earthy patches, involving a large portion or entire circumference of the artery, but by the deposition of numerous hard round grains, which had been formed in their coats and projected like so many tubercles both within and without the vessel.

Steenberg,¹² in a Danish monograph in 1860, had shown the causal relationship between syphilitic diseases of the brain and changes in the cerebral arteries, but Wilks seems to have been the first to distinguish clearly between the lesion of arteriosclerosis and that of syphilitic disease of these vessels. This distinction was confirmed by Lancereaux,¹³ in 1866 and by Allbutt,¹⁴ in 1869, and the whole subject of syphilitic disease of the cerebral arteries was put on a firm foundation by the important monograph of Heubner,¹⁵ in 1874.

To return to the subject of aortic disease and aneurysm, which was giving the surgeons of the British army so much concern, in 1873, in a Strasbourg dissertation, Helmstedt¹⁶ gave what was undoubtedly the first accurate description of the aortic lesion associated with aneurysm and pointed out the features distinguishing it from the lesion of arteriosclerosis. He failed, however, to recognize its relationship to syphilis.

Uncertainty regarding the essential etiologic factors still ruled when on Nov. 23, 1875, Francis H. Welch,¹⁷ assistant professor of pathology in the Army Medical School at Netley, England, presented before the Royal Medical and Chirurgical Society of London his paper, entitled "On Aortic Aneurysm in the Army and the Conditions Associated with It"—a paper which Osler,¹ writing in 1909, declared "remains the most important communication upon the subject in English." Welch's paper was based on a study of the aorta in thirty-four

cases of aneurysm from the pathologic records of the Royal Victoria Hospital at Netley, England.

The more one studies this modest contribution of Welch the more one is convinced that it contains almost all the essential facts relating to the etiology and pathology of syphilitic aortitis and aneurysm as they are known today. He found a characteristic lesion of the wall of the aorta, associated in most instances (66 per cent) with syphilis but in a few instances with rheumatic fever or chronic alcoholism, which preceded and was the cause of the aneurysmal dilatation and which consisted of "a diseased condition of the contiguous layers of the internal and middle coats of the vessel—a tissue growth terminating in degeneration—which by impairing the elasticity and contractility of the walls, allows of their expansion and dilatation under the tension of normal blood pressure, or this abnormally increased by any cause."

He noted that the process began at the root of the aorta and proceeded distally and that the sinuses of Valsalva were usually involved, as were also frequently the aortic cusps. The process, he declared, might retrogress without serious damage to the system at large, but if extensive or severe was followed by one of three fatal complications—aneurysm, damage to the aortic valve or hypertrophy and dilatation of the heart. Almost the only thing lacking in his description is mention of the proneness of the aortic lesion to encroach on the mouths of the coronary arteries.

In particular, he emphasized the distinction between this process and the usual form of atheroma which sometimes accompanies it and which, he maintained, never produces aneurysm and at the age of aneurysm is innocuous.

The description of the gross appearances of the early lesion in the aorta is graphic and accurate. In his histologic description he failed to emphasize the destruction of the elastic tissue in the media, which is so characteristic a feature, but he repeatedly referred to the loss of elasticity caused by the changes in the middle coat. With respect to prophylaxis, Welch concluded that since syphilis is the chief cause of the disease, effective measures for the prevention of aneurysm must deal with the suppression of syphilis.

The importance of Welch's contribution was entirely overlooked. The opinions expressed were vigorously opposed by his nonmilitary English colleagues and were completely ignored in other countries. The facts concerning syphilitic aortitis were years afterward to be rediscovered and newly presented by German pathologists before Welch received his meed of credit. Osler,¹ in 1909, quoted from a letter just received from Colonel Welch referring to the reception given to his paper.

The only individual who gave me the slightest support in 1876 was Sir James Paget, and since then one or two others have written giving their experience, but for long after, as could be seen in the narration of annual cases in the professional journals, there was a dead set against my deductions.

Almost immediately after the appearance of Welch's paper there were published two reports by Heiberg¹⁸ describing the characteristic aortic changes, including those of the media, ascribing them to syphilis and distinguishing them sharply from those of atherosclerosis. Heiberg's contribution also was destined to remain long unnoticed.

The beginning of the final struggle for the recognition of the specific nature of syphilitic aortitis dates

from the appearance, in 1885, of the thesis of Dohle¹⁹ who reported from the pathologic institute of Heller in Kiel a carefully studied case of aortic disease in a man of 25 years who showed many evidences of severe late syphilis. He emphasized the changes in the media, ascribed to these the peculiar appearance of the aorta and noted the slight involvement of the intima in contrast to that seen in the usual type of arteriosclerosis.

Before any further reports appeared from Heller's laboratory, Malmsten²⁰ published an important monograph showing statistically the great frequency of syphilis in aortic aneurysm and giving an accurate description, with illustrations, of the gross appearances of the aorta, together with microscopic changes which he described as a "sclerogummatous" process. Although his microscopic description was incorrect in certain details, Malmsten's contribution was important and deserved much greater recognition than was accorded it in Germany when the battle had been won and the identity of syphilitic aortitis had been established.

Dohle's first report was followed, during the decade beginning with 1890, by a series of careful studies by various workers in Heller's laboratory, including a second paper by Dohle,²¹ in which most of the details of the microscopic picture of syphilitic aortitis were fully described. Nevertheless, these views continued to meet with opposition from most of the representative German pathologists. How strong this opposition was was made clear at the meeting, in 1899, of the Deutsche pathologische Gesellschaft,²² at which Heller defended the views of the Kiel school as to the specific nature of the aortic lesion associated with aneurysm (syphilitic mesaortitis) and emphasized the features distinguishing it from atherosclerosis. Heller's views were supported by Straub,²³ who in a paper giving the results of post-mortem examination in a large number of cases of dementia paralytica reported that the lesions described by Dohle and Heller were found in the aorta in 82 per cent of the entire group of patients and in 92 per cent of the men. The prolonged discussion which followed these presentations shows that the majority of those taking part were still unwilling to accept the view that the specific character of syphilitic aortitis had been established. It was not until the meeting of the same society in 1903, at which the subject was again considered, that the correctness of the claims of the Kiel pathologists was generally admitted and the "Dohle-Heller" type of aortitis given full recognition. In the vast amount of study which since that time has been devoted to the histologic features of syphilitic aortitis, increasing emphasis has been laid on the early obliterative changes in the vasa vasorum of the adventitia as the important factor in producing the destructive lesions in the media. For this reason Scott and Saphir²⁴ expressed the belief that the name "mesaortitis syphilitica" is somewhat misleading and that the term "aortitis syphilitica" is to be preferred. Reuter,²⁵ in 1906, was the first to report the finding of spirochetes in the aortic lesion, and this discovery was promptly confirmed by Schmorl²⁶ and later by Wright and Richardson,²⁶ who recovered the organisms in five cases of aortitis. Nevertheless, later experience has shown

that such positive findings are extremely rare. According to Herxheimer,²⁷ in 1931, only about fourteen trustworthy instances of such positive findings in syphilitic aortitis are recorded.

If further confirmation was needed, it was furnished by the results of the Wassermann test, first reported in 1908, by Frankel and Much,²⁸ who demonstrated a positive reaction in nineteen of twenty-three cases in which typical mesaortitis was found at autopsy. The association of aortic insufficiency with tabes dorsalis had been noted by Berger and Rosenbach,²⁹ in 1879, and that of aortic aneurysm with dementia paralytica by Bordes-Pages,³⁰ in 1887, but without any clear understanding as to what these associations signified. In 1901, Babinski³¹ emphasized the frequency with which the early signs of tabes (changes in the pupils and deep reflexes) were found in connection with aortic aneurysm—a combination of symptoms to which Vaquez later gave the name of the "Babinski syndrome."

Before leaving the subject of aortitis, attention should be called to the important contribution made by Curschmann,³² in 1893, to the clinical diagnosis of that disease in his paper, entitled "Sclerosis of the Thoracic Aorta." It is evident that most, if not all, of his cases were instances of syphilitic aortitis, although he did not recognize them as such. In his discussion of the symptoms he referred to sudden attacks of angina pectoris even when there was no evidence of involvement of the heart, and among the physical signs he laid emphasis on the supracardiac dulness, the prominent pulsation in the jugular notch, the frequent occurrence of pulsus differens and, especially, the peculiar accentuation and ringing quality of the aortic second sound. He was much impressed with the diagnostic importance of the change in the second sound and stated that it is probably due to the stretching of the aortic cusps from the dilatation of the root of the aorta. This, so far as I am aware, is the first notice of the peculiar change in the aortic second sound which has since been so closely identified with the diagnosis of syphilitic aortitis. Allbutt,³³ in discussing this sound, implies that it was first noted by Potain, who gave it the name "bruit de tabourka" (tabourka being the name of an Arab drum) but according to Vaquez³⁴ that term was applied by Potain to a peculiar change observed in the heart sound either the first or the second, in acute endocarditis.

Concerning syphilitic disease of the heart itself, the ancient writers had little to say that will bear scrutiny. The first well established case was that reported by Ricord³⁵ in 1845, in which there were found a gummatous mass in the heart wall and some thickening of the endocardium. Virchow,³⁶ in 1858, in reporting a similar case pointed out that in the heart, as in the testicles and the liver, late syphilis showed itself either as a gummatous process or as a diffuse fibrous inflammatory change—a classification which with little modification has lasted to the present day.

With respect to the frequency of syphilitic heart disease (apart from changes resulting from aortitis) there has always been a difference of opinion between

the pathologists and the clinicians Whereas the latter have been inclined to look on cardiac syphilis as a not uncommon condition, the former, with few exceptions have insisted on the comparative rarity of instances of disease which post mortem can be identified positively as syphilitic This discrepancy is doubtless to be explained, in part at least, by the great difficulty in establishing proof of syphilis when the lesion found consists only of fibroid change or scars, for it seems to be the almost universal opinion among pathologists that such lesions, when syphilitic, usually present no histologic features by which they can be distinguished from fibrotic and cicatricial changes due to other causes, and that the demonstration of spirochetes in such tissues is rarely possible

In contrast to this position are the well known views of Warthin,³⁷ who was convinced that the essential lesion of late syphilis is not the gumma, which is relatively rare, but "an irritative or inflammatory process, usually mild in degree, characterized by lymphocytic and plasma-cell infiltrations in the stroma, particularly about the blood vessels and lymphatics, slight tissue proliferations, eventually fibrosis and atrophy or degeneration of the parenchyma" These microscopic changes he believed to be specific and diagnostic, and frequently in the neighborhood of such small lesions he was able to demonstrate the presence of spirochetes Using these criteria, Warthin insisted that myocardial lesions in late syphilis are extremely common and that even when no myocardial changes are visible to the naked eye the microscope may reveal "the most extensive lesions"

Fifteen years have passed since the publication of these statements by Warthin and yet, so far as I am aware, they have thus far received no confirmation or acceptance by pathologists either in this country or abroad The whole subject has been thoroughly discussed by Clawson and Bell,³⁸ by Herxheimer,³⁷ and within the last year also by Saphir,³⁹ who in a histologic study of the hearts of 130 patients with syphilitic aortitis with aortic insufficiency could find no instance of myocardial change which could be interpreted as that of syphilitic myocarditis Neither was he able, by the use of the Warthin-Starzy method, to find spirochetes in any of the cases, although the method revealed artefacts that resembled spirochetes

One can conclude only that if the lesions of late acquired syphilis are common in the myocardium they exist in forms which render them indistinguishable from those due to other and more probable causes

A question of almost equal importance to the clinician is that relating to the frequency with which the coronary arteries are the seat of syphilitic changes As to the almost constant encroachment on the *mouths* of the coronaries found in well developed cases of aortitis there can be no doubt,⁴⁰ but the question of the occurrence of syphilitic changes in the arteries themselves is one concerning which there is again wide discrepancy between the findings of the pathologists and the popular belief among internists It has long been a cherished conviction of the latter that signs of coronary disease in persons in early middle life should always arouse strong suspicion that the coronary lesion is syphilitic The importance of syphilis in coronary disease has

been emphasized especially by the French writers, some of whom have gone so far as to regard syphilitic disease as the commonest cause of myocardial infarcts (Letulle)⁴¹ Yet pathologic evidence to support the view that specific syphilitic changes are common in the course of the coronary vessels seems to be scanty (Herxheimer,³⁷ Turnbull,⁴² Martland,⁴³ Saphir³⁹) The assumption that manifestations of coronary disease are necessarily due to syphilitic changes in the arteries because they appear in persons known to be, or suspected of being, syphilitic is obviously unjustified in view of the accumulated mass of evidence indicating the frequency with which atherosclerotic changes in those vessels are found in persons in the fourth and fifth decades of life

From the evidence at hand it seems safe to say that syphilis is rarely a cause of coronary disease except as it involves the proximal portion of those vessels as a part of the process of aortitis Moritz⁴⁴ recently showed that the encroachment on the lumens of the coronary arteries in the course of syphilitic aortitis is due not solely to the aortic lesion but frequently to associated endarteritis which is limited to the first 10 or 12 mm of the vessel

Syphilitic disease of the pericardium and endocardium was frequently referred to by the older writers, but most of the reported instances have not withstood critical investigation If one excludes the frequent cases in which involvement of the aortic cusps is the direct extension of a syphilitic process in the aorta and the rare instances of disease of the pulmonary valve as a part of a similar process in the pulmonary artery, only a few well authenticated examples of syphilitic valvular disease remain Staemmler⁴⁵ recorded an instance of involvement of the anterior cusp of the mitral valve by extension of the syphilitic process from the aortic valve in a case of aortitis A few other instances are on record of mitral disease due to extension from a syphilitic lesion in the myocardium, but Herxheimer³⁷ was emphatic in his assertion that anatomically proved instances of primary syphilitic changes in the mitral or tricuspid valves are unknown

The subject of mitral stenosis should not be left without reference to a report of Amblard,⁴⁶ who, after observation of 165 cases of mitral stenosis among French soldiers during the World War, reached the conclusion that most of these cases were the result of congenital syphilis The paper is convincing neither as to the diagnosis of mitral stenosis nor as to the evidence of syphilis

Syphilitic changes in the pericardium have been recorded occasionally from the time of Morgagni In almost every well authenticated case the process has been due to extension of the lesion either from the myocardium or from the aorta In a few instances the process was gummatous, more frequently it consisted of fibrous adhesions and thickenings chiefly about the base of the heart and the great vessels, rarely it was so extensive as to cause concretion pericardii

With respect to the involvement of the heart in the early stage of syphilis there are clinical observations going back to the time of Fournier,⁴⁷ in 1873, who noted various disturbances of cardiac function but

ascribed them to nervous influences rather than to anatomic changes. With the growth of experimental evidence as to the very early invasion of the lymph and blood streams by the exciting organisms, it has become increasingly evident that reactive changes in the viscera begin early, and that in the case of the heart symptoms of such early reactive changes may appear. As confirmation by autopsy has rarely been possible in such cases, the interpretation of the various minor subjective symptoms and physical signs has depended on the clinical judgment and discrimination of the individual observer, and as might be expected under such circumstances, the conclusions of different writers have varied greatly. Grassmann,⁴⁸ for example, found evidences of what he regarded as involvement of the heart in more than two thirds of the 288 cases studied.

In the reports of L. Braun,⁴⁹ Amelung and Sternberg,⁵⁰ Brooks,⁵¹ Howard,⁵² Lukomski,⁵³ and others the incidence of cardiac symptoms in the early stage varied between 8 and 33 per cent. On the other hand, in a very careful and complete study of the heart in fifty cases of early syphilis Turner and White⁵⁴ could find no definite clinical evidence of disease of the heart or aorta in any case.

There is, however, anatomic evidence to prove that occasionally the type of lesion characteristic of the late stage of syphilis (e. g., aortitis and aneurysm) may occur very early—even within a few months of the date of the infection. Brooks⁵¹ cited two such cases, and records of similar instances are found scattered through the literature. Schlesinger⁵⁵ stated that during the World War and the "hunger years" it was not uncommon to find within a few months after infection vascular and nervous manifestations that ordinarily were to be seen only many years later as phenomena of the late stage of syphilis.

Involvement of the pulmonary artery in late syphilis has long been recognized as an occasional but rare phenomenon. If Pare's statement, already quoted, is to be credited, to him belongs the distinction of having first described such a case.

The rarity of fully established instances of the disease may be seen from the careful study of Karsner⁵⁷ which has just appeared. He included among the proved cases nine in which there was either simple formation of gummas or gummatous arteritis and eleven, including his own, in which the process was of the productive-cicatrical type commonly found in the aorta. These twenty cases of syphilitic disease constitute only a small fraction, of course, of the number of cases reported as such in the literature. Six of the twenty cases were associated with saccular aneurysm, and permanent dilatation of some degree was found in all the remaining cases. In about one half of the cases there was concomitant syphilitic aortitis, but the evidence is not conclusive that in such cases the lesion in one vessel is due to extension from the other. Recently Laubry and Thomas⁵⁸ (and others) have

attempted to develop the clinical picture of syphilis of the pulmonary artery and have expressed the belief that in a certain number of such cases a clinical diagnosis is possible.

Syphilis of the pulmonary artery cannot be discussed without reference to its relationship to the syndrome known as Ayerza's disease. At the present time this relationship is most uncertain, and there is increasing evidence to show that sclerosis of the smaller branches of the pulmonary artery which seems to be the essential lesion underlying the clinical picture of Ayerza's disease, may be due to various causes other than syphilis. Cheney's⁵⁹ suggestion, therefore, that the term "Ayerza's disease" be restricted to those cases in which the syndrome is due to syphilitic changes in the pulmonary artery seems hardly logical.

In considering the incidence of syphilitic disease in the arteries other than the aorta, a distinction must be made between the lesions involving the orifices of the vessels given off from the aorta as a part of the disease process in the aorta and lesions occurring in the course of the arteries and independent of the aortic process. Changes of the former type have long been known to be common. Snow,⁶⁰ of Albany, N. Y., in 1880, made one of the early reports under the title, "Syphilitic Degeneration of the Arteries as a Cause of Aneurysm", one of his two cases of aneurysm showed also occlusion of the left subclavian artery. Straub,⁶¹ in 1899, in recording his large series of autopsies on patients with dementia paralytica emphasized especially the tendency in aortitis to encroachment on the mouths of the large arteries given off from the arch as well as on those of the coronary arteries. Turnbull⁶² in 175 autopsies in cases of syphilitic aortitis found the orifice of the innominate artery involved 23 times and that of the left subclavian artery, 10 times. Toppich⁶³ spoke of the frequent narrowing of the orifices of the intercostal arteries and of the possible clinical significance of this. Information concerning the incidence of syphilitic disease in the course of the arteries has been much less certain. The pathologists generally have thought that such syphilitic changes were uncommon, although the comparative frequency of aneurysm in the larger arteries would seem to speak to the contrary. Warthin⁶⁴ found simple atherosclerosis much commoner in syphilitic patients than in nonsyphilitic patients of corresponding age and regarded the condition as related to syphilis, although probably not a result of the direct action of the spirochetes. The latest study of this subject is that of Saphir,⁶⁵ who took sections of most of the larger arteries in fifty cases which at autopsy presented syphilitic lesions in the aorta. Among these fifty cases characteristic syphilitic changes were found in the innominate artery in thirty-three, in the carotid artery in twenty-nine, in the superior mesenteric artery in ten and in the femoral artery in seven. Changes were found in the subclavian artery in fifteen of twenty-nine cases.

In the medium-sized and smaller arteries of the extremities characteristic syphilitic changes, with marked proliferative changes in the intima and a tendency to thrombosis, have been found occasionally, but in this instance as in so many others there is a difference of opinion between the pathologists and the clinicians as to the frequency of the changes. the cases of syphilitic disease of the smaller arteries of the legs have clinically borne a close resemblance to thrombo-angitis obliterans, but Buerger,⁶⁴ along with most other writers, was convinced that syphilis plays no part in the etiology of that disease.

Syphilis of the arteries of the brain remains the commonest and the best studied example of the syphilitic process in the medium-sized and small arteries. In spite of the fact that it was the first form of syphilitic vascular disease to receive general recognition, thanks to the monograph of Heubner, it was nevertheless many years later before pathologists were in agreement as to certain fundamental facts concerning it. The question as to whether the change actually began as a proliferative process in the intima, as Heubner believed, or whether the proliferation of the cells of the intima was secondary to an inflammatory process in and about the vasa vasorum of the adventitia, as was maintained by von Baumgarten and many others, was long in being settled. The final judgment seems to have been in favor of the essential unity of all syphilitic disease in the arteries as a process which proceeds from without inward through the primary involvement of the nutritive vessels of the adventitia.

Knowledge concerning the manifestations of syphilis in the veins was for a long time limited to occasional clinical reports of instances of phlebitis of one of the superficial vessels which occurred in patients with other evidences of syphilis or which in patients suspected of having syphilis responded promptly to antisyphilitic treatment.

Credit for the first trustworthy record of this kind is given to a British army surgeon, Girdwood,⁶⁵ who reported three cases. In 1898, Proksch⁶⁶ was able to assemble 107 instances of syphilis of the larger veins, some of them of doubtful validity. Much the most important contribution to the subject, however, was made by E. Hoffmann,⁶⁷ in 1905.

The forms of syphilis of the veins of chief interest to the clinician are those which belong to the secondary stage of the disease and which occasionally are seen even before the appearance of the cutaneous eruptions. They involve almost exclusively the subcutaneous or cutaneous veins. Hoffmann distinguished three types, diffuse (*strangiforme*) phlebitis, nodular periphlebitis (nodose syphilid) and erythema nodosum syphiliticum. Subsequent studies have confirmed the careful work of Hoffmann and have made it clear that these syphilitic involvements of the veins of the secondary period have considerable clinical importance.

The venous lesions of late syphilis appear to be much less common and are certainly much less characteristic. The deep veins of the trunk are the ones usually affected, and the lesion apparently may either be primary endophlebitis or consist of periphlebitic gummatous inflammation which is often an extension from neighboring syphilitic disease. The interesting and rare obliterating endophlebitis of the hepatic veins seems to be in most instances at least, a syphilitic process and the same is true of certain of the cases of primary sclerosis of the portal vein.

What has been said thus far has referred entirely to the changes wrought in the cardiovascular system by the acquired form of syphilis. There is time now for only a word concerning the knowledge of the effects of

congenital syphilis on the circulatory system. In general, it may be said that that knowledge is in some respects on a firmer basis in the case of congenital syphilis than in the case of the acquired form. Proof of the specific nature of the changes has been easier to obtain because of the relative frequency with which the spirochetes have been found and because of the rarity at that time of life of lesions due to other causes which might be confused with those due to syphilis.

The circulatory lesions produced by acquired syphilis for the most part have their counterparts in those which are found in congenital syphilis. Myocardial changes are infrequent and consist usually of a diffuse or a circumscribed form of myocarditis. Actual gummas are rare. The commonest lesion is aortitis, which corresponds in all essentials to the early stage of the acquired type and can be recognized often in syphilitic infants who are stillborn or who die soon after birth. In the late congenital form of the disease the clinical picture of aortitis, of aortic aneurysm and of aortic insufficiency, though rarely seen, resembles closely that of acquired syphilis. Among the medium-sized and smaller arteries, those of the brain have been most often found involved, and instances of such involvement are recorded even in very young children.

Knowledge that the vessels of the umbilical cord may be the seat of syphilitic disease dates from 1870 (Oedmannsson⁶⁸), and this subject since then has been given much study. To the close relationship between the umbilical vein and the liver is ascribed the great frequency of involvement of the liver in congenital syphilis, and the same explanation is offered for the rare instances of syphilitic peripylephlebitis found among syphilitic children. The relation of obliterating endophlebitis of the hepatic veins to congenital syphilis has been emphasized in a recent study by Beitzke.⁶⁹ Types of phlebitis corresponding to those seen in the secondary stage of acquired syphilis have not been recorded in connection with the congenital form.

This attempt to review briefly the steps by which has grown the present knowledge of the relation of syphilis to disease of the cardiovascular system has resulted in a mere sketch of some of the more conspicuous landmarks along the way. Many important facts and many important names have not been mentioned. What has been said, however, must have made clear the devastating effects of this wholly preventable infection on the vital organs of circulation. It would be easy, if time permitted, to muster statistics showing the distressing prevalence of cardiovascular syphilis and the size of the problem in preventive medicine that it presents. But statistics are not necessary. All physicians know that syphilis heads one of the three great etiologic groups of cardiovascular disease. They know that it accounts for from one sixth to one fourth of the deaths from such diseases among adults. And, finally, they know that at the present time the syphilitic group is the only one of the three great classes for which preventive measures are known and are available. Are they making the most of this knowledge? Are they really doing everything that is reasonably possible to prevent syphilis itself or to prevent these grave consequences of syphilis?

The responsibilities are so great and the consequences of success or failure in such efforts are so momentous that these questions must be asked—and answered.

SOME DISORDERS OF THE ESOPHAGUS

ARTHUR F. HURST, MD (OXON), FRCP

Senior Physician to Guy's Hospital

WINDSOR FOREST, BERKS, ENGLAND

The discovery of new clinical syndromes reveals a curious feature of the physician's psychology. As soon as his attention is drawn to the existence of such a syndrome he finds cases with increasing frequency and wonders how such an obvious condition could have escaped his observation in the past. Thus duodenal ulcer was, with few exceptions, never recognized before 1908, when Moynihan at last succeeded in convincing physicians that it was a very common disorder with characteristic symptoms, which Abercrombie had described to an unlistening profession eighty years before. The history of coronary thrombosis is a more recent illustration of the same phenomenon.

I propose to discuss here four esophageal syndromes all of which are still insufficiently recognized, and three of which were quite unknown to me at the time of my last visit to America in 1919. Every physician will I feel sure, recognize them with increasing frequency during the next few years and will wonder what can have happened to the cases which came under his care and which he failed to recognize in the past.

THE DYSPHAGIA OF ANEMIC WOMEN

CASE 1—A woman, aged 41, consulted me in 1926 on account of difficulty in swallowing. Roentgen studies and esophagoscopy did not reveal any organic obstruction, and watching her during a meal showed that the dysphagia was the result of incoordination of the muscles involved in the initiation of the act of deglutition. Her tongue was sore and showed well marked glossitis, the surface being red, smooth and glossy, owing to complete atrophy of the papillae. She was anemic with 3,540,000 red corpuscles per cubic millimeter and 48 per cent hemoglobin, and her spleen was enlarged. Her condition improved greatly as a result of treatment of the glossitis continued with the administration of large doses of iron and ammonium citrate.

I doubt whether I should have paid much attention to this remarkable symptom complex had I not just read a paper by Vinson¹ in which he described a number of similar cases observed by Plummer and himself, though curiously enough he did not refer to the glossitis. I² described the case in a short paper under the rather unfortunate name of the "Plummer-Vinson Syndrome"—unfortunate because I subsequently discovered that excellent accounts of the condition, though without any details as to the type of anemia present, had been published in 1919 by Brown Kelly³ and by Paterson⁴. These papers had appeared in the *Journal of Laryngology* and had thus escaped the attention of internists—one disadvantage of specialization in medical literature.

I have now seen a considerable number of cases, and the condition has gradually become well recognized in England, where papers on the subject have been written by Ryle,⁵ Jones and Owen,⁶ Cameron,⁷ and Witts⁸.

The anemia is almost always of the hypochromic microcytic type, exceptionally it is Addisonian. It is generally associated with achlorhydria or hypochlorhydria, and as the condition apparently occurs only in middle-aged women, the whole syndrome may, as Witts has suggested, be regarded as a complication of simple achlorhydric anemia. In severe cases the anemia is associated with splenomegaly, as Plummer and Vinson first pointed out, but in mild cases this is generally absent.

Atrophic glossitis is constantly present. It differs in no respect from that described in 1900 by William Hunter as characteristic of Addison's (pernicious) anemia. The tongue feels sore in the acute phases, but atrophy of the filiform papillae may occur without any subjective symptoms. The tongue finally becomes smooth and glossy. This condition of the mucous membrane extends to the pharynx and entrance into the esophagus.

The dysphagia is a result of disturbance in the neuromuscular mechanism which causes the relaxation of the normally closed pharyngo-esophageal sphincter formed by the cricopharyngeus muscle directly after the food has been propelled into the pharynx by the tongue. Absence of this relaxation or "achalasia," the significance of which will be discussed presently, is sufficient to cause dysphagia, though in some cases spasm may replace the normal relaxation. The atrophic inflammation of the mucous membrane in the neighborhood must be the cause of this neuromuscular disorder. Either the nerve endings are atrophied and fail to convey the afferent impulses, which result in the reflex relaxation of the sphincter, or the ganglion cells of Auerbach's plexus are involved and fail to convey the efferent impulse to the sphincter. Suzman⁹ was unable to find any abnormalities in the plexus in a patient who had died from mediastinitis and empyema following the passage of an esophagoscope as, however, the part in which such changes would be most likely to be present was disorganized as a result of acute inflammation following the perforation this can not be regarded as conclusive evidence against the view that organic disease of the nervous tissue at the pharyngo-esophageal junction is the cause of the dysphagia. In the earlier stages the neuromuscular tissues may be in a condition of abnormal irritability so that spasm instead of achalasia results.

Plummer and Vinson regarded the dysphagia as hysterical and the anemia and splenomegaly the result of secondary malnutrition, though dysphagia due to other causes does not lead to splenomegaly and only rarely to anemia. They had failed to observe the constant association of the dysphagia and anemia with glossitis, which is a common accompaniment of simple achlorhydric anemia in the absence of dysphagia, the latter condition, when it is present, must be caused by spread of the inflammation to the pharyngo-esophageal junction.

There is no doubt that many of the patients are of a nervous temperament and that the condition may be exaggerated by autosuggestion. But this is also true for other conditions, which I shall presently describe as causes of dysphagia, although they are quite certainly organic in origin.

The anemia is rapidly cured by the same treatment as that required for uncomplicated cases of simple achlorhydric anemia—the administration of 30 grains (2 Gm) of iron and ammonium citrate three times a day after meals—and the condition of the tongue improves with liver extract. The dysphagia can be cured by the passage of mercury bougies of increasing diameter, occasionally a single treatment is sufficient, though in cases in which spasm and not achalasia is present considerable difficulty may be experienced in passing the instrument.

ACHALASIA OF THE CARDIAC SPHINCTER (SO CALLED CARDIOSPASM)

A condition in which enormous dilatation and hypertrophy of the esophagus occurs without organic obstruction has long been recognized by morbid anatomists, and for many years the theory first suggested by Mikulicz in 1888 that the condition was due to spasm of the cardiac sphincter was widely accepted. The investigation of a case in 1913 led me, however, to reject this theory. I found that a rubber tube, filled with mercury dropped into the stomach without meeting any appreciable resistance in its passage though the cardia, could be withdrawn with equal ease, in striking contrast with the firm resistance offered to the examining finger by a spasmodically contracted anal sphincter in cases of anal ulcer and with the grip exerted on the finger when it has once entered the rectum. Moreover, the cardiac sphincter has never been found to be hypertrophied after death, and in operations in intractable cases the part of the sphincter within the abdomen is of normal thickness or even rather atrophied, although spasm lasting continuously for many years would certainly lead to hypertrophy. It seemed

tion opens the passage and removes the obstruction previously present. Although the cardiac sphincter is not described in the majority of textbooks on anatomy, there is no doubt from anatomic and radiologic studies that one exists. It is normally about an inch in length, its upper end being generally on a level with the hiatus oesophageus, but it is occasionally lower than this and in rare cases the whole of the sphincter is thoracic, with the cardiac orifice of the stomach in contact with

Fig 2—Esophagus in achalasia of cardia. A column of barium containing food 8 inches high above closed cardia. B after additional quantity of food has been swallowed so that the taller column being heavier opens cardia and allows surplus to enter stomach. C return to condition of A after surplus of food over the 8 inch column has entered stomach.

the diaphragm. So long as no short synonym of “absence of relaxation of the cardiac sphincter” was available, it was clear that the old name of cardiospasm would hold the field, in spite of the fact that there was no evidence that spasm was ever present in uncomplicated cases. I therefore asked Sir Cooper Perry to invent a name, he suggested the excellent word achalasia, derived from *a*, absence of, and *χάλασις*, relaxation.

In 1913, after I had demonstrated a case of achalasia of the cardia at the Royal Society of Medicine, Sir Humphry Rolleston told me that he had suggested a similar explanation when showing a postmortem specimen to the Pathological Society in 1896. I subsequently discovered that Dr Max Einhorn¹⁰ had anticipated Sir Humphry by eight years. Now Dr Ralph Major of the University of Kansas has drawn my attention to the following remarkable account of achalasia of the cardia by Thomas Willis in his *Pharmaceutice rationalis*, which was published in 1672, and in which both the idea of achalasia and the modern treatment are foreshadowed.

No less will a very rare case of a certain man of Oxford show, an almost perpetual vomiting to be stirred up by the shutting up of the left orifice. A strong man, and otherwise healthful enough, labouring for a long time with often vomiting, he was wont very often, though not always, presently to cast up whatsoever he had eaten. At length the disease having overcome all remedies, he was brought into that condition, that growing hungry he would eat until the oesophagus was filled up to the throat, in the meantime nothing sliding down into the ventricle; he cast up raw (or crude) whatsoever he had taken in when that no medicines could help and he languished away for hunger, and every day was in danger of death, I prepared an instrument for him like a rod, of a whale bone, with a little round button of sponge fixed to the top of it, the sick man having taken down meat and drink into his throat presently putting this down in the oesophagus, he did thrust down into the ventricle, its orifice being opened, the food which otherwise would have come back again, and by this means he hath daily taken his substance for fifteen years and doth yet use the same machine, and is yet alive and well.

Fig 1—Passage of a bolus of barium-containing food (B) through the esophagus (O) as seen with roentgen rays in successive seconds after swallowing. S spine H heart D D diaphragm C C cardiac sphincter F fundus of stomach.

to me much more probable that the obstruction was caused by absence of the relaxation of the sphincter, which normally occurs when, in the act of swallowing, a peristaltic wave reaches it (figs 1 and 2). A sphincter muscle differs from other muscles in having relaxation as its normal activity, at rest its postural tone is such that it completely obliterates the lumen of the passage which it surrounds and in activity its relaxa-

who would otherwise perish for want of food. Without doubt in this case the mouth of the stomach being always closed either by a tumour or pulse nothing could be admitted into the ventricle unless it were violently opened.

It seemed to me likely that the achalasia was not a purely functional condition but would prove to be the result of some organic change involving the neuromuscular control of the sphincter. In 1925 Dr Geoffrey Rake,¹¹ at that time a medical student at Guy's Hospital, proved that this was the case. At a post-mortem on a man who died from pneumonia without having suffered from dysphagia the esophagus was found to be hypertrophied but not dilated, he thought that this might represent the earliest stage of the condition, in which the hypertrophied esophagus was still able to overcome the resistance offered by the sphincter, so that no dilatation had yet occurred. With the help of the late Prof. Adrian Stokes he demonstrated a round-cell infiltration of Auerbach's plexus at the lower end of the esophagus (fig 3). During the next few years he had the opportunity of examining Auerbach's plexus in ten specimens obtained from various sources and without exception degenerative changes resulting in more or less complete disappearance of the ganglion cells were found (fig 5). Rake's results have since been confirmed by Cameron¹² in eight cases and by Mosher and McGregor¹³ and by Beattie¹⁴ in one each. It is clear, therefore, that this apparently functional condition is really the result of organic disease of Auerbach's plexus, achalasia of the cardia is in fact the only well established example of a localized disease of the autonomic nervous system.

The closed cardiac sphincter can support an 8-inch column of water. Consequently in achalasia the dilated esophagus is constantly filled with a mixture of food and saliva 8 inches high. When more food is taken the cardia opens and allows some of the esophageal contents to enter the stomach but it closes again directly the column falls to the 8 inch mark (fig 2B). Owing to the fact that the pharyngo-esophageal sphincter is normally closed, nothing escapes from the dilated esophagus when the patient lies down.

TREATMENT

Achalasia of the cardia can be cured in a large majority of cases by the use of a wide tube containing mercury.¹⁵ This treatment is quite devoid of danger in contrast with the Russell-Plummer dilator which has led to a number of deaths from mediastinitis and peritonitis. In the very rare cases in which the dilatation is so extreme and has led to such an increase in the length as well as in the diameter of the esophagus that a part of it reaches below the entrance into the cardiac sphincter, it may prove impossible for the mercury bougie to find its way into the stomach, and it consequently coils up within the esophagus. In such cases the sphincter should be stretched from below by fingers introduced through the stomach as first practiced by Mikulicz in 1882, this operation gives much better results than longitudinal incision of the sphincter.

(Heller) or esophagogastrostomy (Eckner), both of which I have known to fail completely.

CHRONIC PEPTIC ULCER OF THE ESOPHAGUS

CASE 2—A woman, aged 35, consulted me in May 1932 on account of a burning pain below the xiphisternum which occurred while eating. It had been present with intervals of complete freedom for six years but had become more constant during the last twelve months. The food felt as if it stuck at the cardia before passing into the stomach, and this sometimes led to effortless vomiting. The pain, which sometimes passed through to the back, was relieved by alkalis and could be completely prevented by taking only fluid food. Roentgen studies had been made in 1927 and again in 1931, but nothing abnormal was found. A diagnosis of gallstones was made on the latter occasion but at operation the gallbladder and other abdominal organs appeared to be healthy and the appendix was removed. When I saw her she was much emaciated and the hemoglobin percentage was only 64. The possibility of achalasia of the cardia was considered, but a roentgen examination with the usual opaque fluid showed no delay in the passage into the stomach and the esophagus appeared to be normal. On reconsideration the presence of pain, which is rare in achalasia, its radiation to the back, and its disappearance with fluid food made a diagnosis of achalasia improbable. As pain was present only with solid food a solid meal mixed with barium was given. Pain was produced and a remarkable picture was obtained: the cardiac sphincter, recognized by the presence of two longitudinal folds, was seen to be widely open, and immediately above it was a round shadow, which could be nothing else but the crater of a large ulcer at the extreme lower end of the esophagus just proximal to the sphincter, above the ulcer the lumen was narrowed as a result of a constant spasm, which led to a moderate degree of stasis in the esophagus but was insufficient to cause any secondary dilatation. The diagnosis was confirmed by esophagoscopy and by the presence of occult blood in the stools.

Failure to recognize the true nature of the condition may have a deplorable effect on the patient's nervous system.

CASE 3—A man aged 78 had suffered from "gas pains" since 1926. In 1929 and again in December 1931 he had a small hematemesis on both occasions roentgen studies were made but nothing beyond an excess of gas in the stomach was discovered. Early in 1932 he began to suffer from dysphagia with excessive salivation, he experienced difficulty in initiating the act of swallowing but he recognized that there was an obstruction at the entrance into the stomach, as the passage seemed to 'shut up' in a painful spasm whenever food reached it this being followed by regurgitation of the food with an excess of mucus. A roentgen examination again showed no abnormality except an enormous gas bubble in the stomach which caused the left half of the diaphragm to be elevated above the right, corresponding with the fact that he complained of very painful flatulence with complete inability to belch and so to obtain relief. His condition was regarded as hysterical and he was treated by various forms of psychotherapy on the continent, in America and in England, but without success. Indeed his condition became progressively worse, and when I first saw him in January 1933 he was in a deplorable state of nervousness and was terrified at the mere idea of eating. When a meal was brought into his room, his face became anxious and his hands shook. Several minutes elapsed before he could persuade himself to lift the fork in his trembling hand to his lips, he masticated much longer than was necessary in order to put off the moment of swallowing as long as possible, at the same time shaking his head. He had lost much weight and strength and was extremely depressed.

As it seemed impossible that such severe dysphagia could be purely nervous in origin, especially in view of the history of the hematemesis, a further roentgenologic examination was made and Dr P J Briggs succeeded in demonstrating the presence of a deep chronic ulcer in the extreme lower end of

the esophagus (fig 6) Endoscopic examination showed the presence of well marked esophagitis, but a persistent spasm near the lower end of the esophagus prevented the ulcer itself from being seen A large quantity of occult blood was constantly present in the stools The enormous gas bubble in the stomach was clearly due to the esophageal spasm caused by the ulcer interfering with the escape of swallowed air upward, just as it interfered with the passage of food downward

Both patients were treated with a milk diet, alkalis and atropine and rapidly lost the pain and dysphagia The old man soon became comparatively happy, but the physical signs of fear, which occurred when food was brought into his room, persisted in a lesser degree after the disappearance of the associated emotion, presumably as a result of a conditioned reflex The ulcers became much smaller in both cases, but after many weeks they had not healed, apparently owing to the associated spasm in the woman and owing to the development of cicatricial narrowing in the man, and eventually gastrostomy was performed This resulted in complete healing with disappearance of the occult blood The woman's stomach was allowed to close and she was able to swallow well chewed food without difficulty, in spite of the development of a slight stricture at the site of the ulcer Complete obstruction developed in the man, but this would probably have been overcome by gradual dilation had not a rapidly fatal attack of acute mania developed

From my experience of these two cases and one other case I shall in future advise a temporary gastrostomy directly after the diagnosis has been made, unless the patient is seen within a year of the development of symptoms, when a fluid diet with alkalis and atropine is likely to lead to a cure, as shown by the experience of Friedenwald and his colleagues¹⁶ If cicatricial stenosis should occur, this can be treated by gradual dilation before the stoma is allowed to close

Peptic ulcer of the esophagus is generally regarded as a very rare condition Stewart observed a single case in 10,000 consecutive postmortems, and Tileston was able to collect only eight cases from the literature in 1909 Twenty years later, Stewart and I¹⁷ collected eleven more, excluding a remarkable series observed by Chevalier Jackson,¹⁸ who had seen twenty-one active ulcers and scars of sixty-seven healed ulcers in 4,000 endoscopic examinations on patients with esophageal disease Jackson believed that the condition would be found to be not uncommon if more carefully looked for, and Friedenwald, Feldman and Zinn came to the same conclusion, as they were able in 1929 to publish records of no less than thirteen cases from their own practice in which a diagnosis had been made with roentgenography and esophagoscopy They are the only authors who have hitherto succeeded in visualizing the crater of an esophageal ulcer with the x-rays, though spasm was observed in several of Jackson's cases Their description of the symptoms agrees closely with those given by Jackson and the earlier reporters of single cases, and also with the cases here reported Discomfort or pain occurs under the lower extremity of the sternum while solid food is being eaten and less frequently half an hour or more after meals It often radiates to the back At first it lasts for only a few minutes and is relieved by alkalis, but later it is prolonged and followed by regurgitation, so that the patient often becomes afraid to eat Hematemesis,

which may be severe and fatal, is a common complication, but perforation into the mediastinum, pericardium or peritoneum is the usual cause of death A fibrous stricture may develop and lead to more or less complete obstruction

An esophageal ulcer has all the anatomic characteristics of a chronic ulcer of the stomach or duodenum In 1899 Fraenkel¹⁹ noticed the presence of heterotopic mucous membrane in the esophagus of a patient dying from an esophageal ulcer, and the same observation was made by Tileston²⁰ in 1906 and by Stewart and Hartfall²¹ in 1929 The heterotopic mucous membrane probably secretes acid gastric juice, which collects in the lower extremity of the esophagus immediately above the closed sphincter, and in the course of time an erosion and finally a chronic ulcer develops This would explain why the ulcer is always situated just above the sphincter The condition is analogous with the peptic ulcers occasionally found in Meckel's diverticula, which

Fig 3—Section of a normal ganglion of Auerbach's plexus in the lower end of the esophagus $\times 50$

are also always associated with the presence of ectopic gastric mucous membrane

THE RECURRENT HIATUS HERNIA SYNDROME OF VON BERGMANN

In May 1931 I visited Prof Gustav von Bergmann's clinic at the Charite in Berlin I found that he was much interested in a particular variety of diaphragmatic hernia,²² a small and generally intermittent form, which he regarded as of great frequency and as responsible for the production of a variety of symptoms Although Friedenwald and Feldman²³ of Baltimore described many of the clinical features of this condition and the special radiologic technic required for its demonstration in 1925, it has remained to a great extent unrecognized, and it has not been clearly separated

from other forms of hernia through the esophageal hiatus in the recent radiologic literature on diaphragmatic hernia

In contrast with the familiar type of nontraumatic diaphragmatic hernia, which results from congenital shortness of the esophagus and of which I have seen thirteen cases in the last ten years, the esophagus in this variety of hernia is of normal length. The tissues that surround it as it passes through the hiatus oesophageus must be abnormally lax. This may sometimes perhaps be congenital, but the greatly increased frequency in elderly persons suggests that it is due mainly to senile changes in the tissues. Under these conditions a slight increase of intra-abdominal pressure is sufficient to push a small segment of the stomach in the immediate neighborhood of the cardia through the hiatus into the thorax. It is generally accompanied by the lower extremity of the esophagus, but occasionally the latter still passes into the abdomen behind, in front of or at either side of the hernia.

The hernia is generally intermittent, but it may become fixed and permanent. Intermittent herniation is produced when the intra-abdominal pressure is increased when the patient bends forward or is in the prone position, in which case the pressure immediately below the hiatus is at its highest.

A hiatus hernia should always be considered as a possible diagnosis when upper abdominal symptoms of doubtful origin occur chiefly or only at night or are associated with slight dysphagia or anginoid symptoms. They generally occur in attacks with periods of complete freedom. Pain or a feeling of pressure may be

sodium bicarbonate or an aerated drink generally gives relief. The attacks are in most cases mainly or exclusively nocturnal and disappear when the patient sits up, severe pain in the night may simulate gallstone symptoms. Intermittent dysphagia may occur. The attacks occasionally follow an emotional upset. The symptoms may be so slight that they are discovered

felt immediately after swallowing under the xiphisternum or a little to the left and occasionally in the back, it may radiate to the heart and to the left shoulder and arm and may closely simulate angina. Acid regurgitation is common, vomiting is sometimes the only symptom. The rapid distention of the stomach which follows aerophagy and the drinking of solution of

only on cross-questioning, and occasionally there are no symptoms at all, the condition being an accidental discovery.

The hernial sac may become inflamed or ulcerated, with the production of hematemesis or occult blood in the stools, and inflammation or ulceration may also occur in the esophagus, which may become slightly dilated above the hernia.

Moore and Kirklin²⁴ of the Mayo Clinic stated in 1930 that "a clinical diagnosis or even surmise of diaphragmatic hernia is scarcely to be expected." It is, however, only by a knowledge of the clinical history of the type of case in which such a hernia is likely to be present that a correct diagnosis can be attained. Intermittent hiatus hernias are never recognized in ordinary routine radiologic examinations, as they are not present when an opaque meal is taken in the erect position. Friedenwald and Feldman showed that they can be most successfully demonstrated when the patient drinks the barium suspension while lying flat on his back, this is also the technic employed by Berg.²⁵ The hernia, which is never larger than a walnut, at once disappears when the patient stands. Knothe²⁶ increases the intra-abdominal pressure by heavy compression and Schatzki²⁷ distends the colon with air, but both maneuvers are likely to produce hernias, which would never develop under natural conditions. The irregular, comparatively thick folds of the fundus mucous membrane can be recognized in the hernia, these are quite distinct from the two or three thin, fine, parallel longitudinal folds in the cardiac sphincter.

TYPICAL CASE OF RECURRENT HIATUS HERNIA

CASE 4—M, a man, aged 65, admitted to New Lodge Clinic in January 1933, complained of attacks of severe abdominal pain, which he has had since 1890. At first there were often intervals of a year or more between attacks, but recently they have become increasingly frequent. The attacks recur daily for periods, which at first rarely lasted for more than a fortnight, but on the present occasion there has been no interval of freedom for several months. Day attacks are brought on by stooping, especially about two hours after a meal. The patient, who has a great deal of writing to do in the course of his profession, has had a very low seat made, so that he is compelled to sit upright at his writing table, and he also frequently writes standing very erect at a high desk. Formerly he found it difficult to carry on with his work, owing to the frequent occurrence of attacks when he leaned over a table to write. He has also found that the attacks, which he formerly had after breakfast, can be prevented by raising his feet to the level of his seat when he puts on his boots.

The nocturnal attacks wake him up regularly about two hours after lying down. They are less likely to occur if he has a pillow under his back than if he lies flat. He can get no relief until he sits up and takes some sodium bicarbonate, as soon as he belches the carbon dioxide set free, he is completely relieved and at once lies down and falls asleep again. Alkalis that do not produce gas and food give no relief.

The attacks are more frequent and more severe when the patient is fatigued or worried.

The pain, which is of a dull boring character and rapidly increases in intensity, is situated high in the center of the epigastrium. It never radiates to the back, upward or downward, or to either side.

Roentgen studies had been made a year before the patient came to the clinic, but nothing abnormal was found. Various diagnoses had been made, but no relief had followed any treatment except that already described, which he had discovered for himself.

Dr T W Turner recognized the history as typical of recurrent hiatus hernia, as described by von Bergmann. A roentgen examination

Fig 6—Crater of large esophageal ulcer

examination carried out in the ordinary way revealed nothing abnormal, but when the patient was examined lying down after swallowing some opaque food without rising, a small hernia was revealed (fig 7). No pressure was applied to the abdomen. It was no longer visible when the erect position was assumed, all the barium having then passed into the part of the stomach below the diaphragm.

CASE 5—A man, aged 68, obtained relief from the frequent nocturnal attacks that he had had for many years by getting up stretching himself and pressing the sides of his thorax till he could bring up wind when the symptoms disappeared and he would quickly fall asleep again. In some of his attacks he felt a suffocating sensation as if his heart was pushed out of place.

PROPHYLAXIS AND TREATMENT

Diurnal attacks can be prevented by avoidance of anything that is likely to increase the intra-abdominal

pressure. The patient should avoid bending and should wear nothing that constricts the abdomen. The presence of carbohydrate intestinal dyspepsia with the resulting intestinal flatulence calls for restriction of potatoes, root vegetables and rice and the administration of diastatic ferment and charcoal. Postprandial attacks of the pain can be prevented by drinking effervescent beverages with the meals.

Nocturnal attacks of the pain can be prevented by reducing the increase in the posterior sub-diaphragmatic pressure by raising the head of the patient's bed as far as possible.

The attacks themselves can generally be stopped by increasing the intra-gastric pressure or by drinking soda water or a solution of sodium bicarbonate. If the patient is lying down, he should sit up. If there is reason to believe that the hernial sac is inflamed, the patient should be given an ulcer diet and should avoid lying flat.

SEMEN APPRAISAL

A DIFFERENTIAL STAIN THAT ADVANCES THE STUDY OF CELL MORPHOLOGY

WILLIAM H CARY, MD

AND
ROBERT S HOTCHKISS, MD

NEW YORK

This paper is presented in an effort to simplify and clarify the essential features of semen examination with special regard to defective spermatogenesis in otherwise healthy men. A new method of fixing and staining a microscopic specimen is detailed, which differentiates component parts of the cell without distorting the protoplasm and enables any physician familiar with the use of the oil immersion lens to recognize and classify abnormal sperm cells, and, in specimens of doubtful character, to count the percentage of these cells as an added index of deficiency or improvement.

Such a contribution seems indicated, for, while the profession and also the public now recognize the potential responsibility assumed by the husband in an involuntarily childless marriage, there is convincing evidence that the more thorough study necessary for properly appraising male reproductive vigor is still unappreciated or not believed and thus incorrect diagnoses are very frequent and much useless gynecologic surgery continues. Not only are urologic and endocrinologic reviews relative to male fertility commonly neglected

From the Department of Urology, New York Hospital

but the examination of the semen, the chief clinical evidence of fecundity, receives but the most elemental consideration. Since 1916, when the senior author first called attention to the importance of lesser semen defects, other investigators have emphasized this factor and presented improved indexes of evaluation, but many practitioners and microscopists in well equipped laboratories continue content with the simple demonstration of viable sperm cells—often a useless if not a misleading gesture. Some well qualified urologists lack the time or the inclination to interest themselves in this special field. Because of certain social and personal aspects of this problem there is danger that progress in knowledge of this subject and application in general practice may be retarded by a cynical reaction to overemphasis of technical details, many of which still belong to the realm of experimental medicine.

Before proceeding, let us emphasize that we are not aiming to define an illusory point at which a mile

efficient evaluation, this subject deserves careful consideration. With due regard for the attitude of the patient, we choose one of the following methods with preference in the order named:

(a) A self-produced specimen at the office of the examiner. If accuracy is stressed and a quiet, suitable room is provided, many men are not averse to this method and the physician is in constant control of the ejaculate.

(b) Collection outside the office by external emission. For this purpose we lend the patient a glass graduate and a small (1 ounce) wide-mouthed bottle. After collection in the former the specimen is allowed to liquefy so that it will not adhere to the glass surface and is then transferred to the bottle. This is corked, placed under the clothing about the torso, and brought to the office.

(c) Condom technique. Patients are advised to prepare the condom in advance by washing the preservative powder from the surface that is to receive the specimen after which it is carefully dried. This precaution is taken because not only do foreign bodies hinder the microscopic examination but there is a chance of harm to the specimen by the various ingredients in these powders. After coitus the condom is tied, gently wrapped in a handkerchief (not clinging absorbent cotton) and is then concealed under the garment next to the skin and thus delivered.

Patients are warned not to attempt artificial warming of the specimen, but on general principles we urge gentleness in handling and the maintenance, as far as possible, of even body temperature. The collection should be made when the husband is in usual good health and at a time of sexual rest in accord with his ordinary habits. Examination of the specimen should be made by appointment preferably not later than an hour after production. The office should be ready for prompt examination when the patient arrives and notation made as to the time of emission, any loss in collection, or deviation from previous instructions. The necessary implements cleansed in plain hot water and thoroughly dried, should be kept ready for the examination. At the appointed hour we plan to have all apparatus, including the microscope, in a heating box not above hot summer temperature, to avoid thermal shock to the semen and the annoyance of misty lenses. Office-procured specimens are put aside in this box for a half hour to allow the temporary thickening of the semen to liquefy. Otherwise a mucoid substance which suspends activity dominates the microscopic field. Condom specimens should be immediately drained in a small glass graduate by an incision in the most dependent part of the sack.

GROSS EXAMINATION

The gross examination includes a notation of the amount, which, when complete, and from men under forty years of age, should exceed 3.5 cm. Lesser amounts should arouse suspicion of deficiency and premature weakening by vaginal acidity, otherwise negligible. Extended periods of sexual abstinence may impart a slightly yellow tinge to the normal grayish opaqueness. Normal specimens commonly show a slight degree of viscosity, which is easily demonstrated by slowly expelling a drop of semen from a pipet. Absence of viscosity with a lessening of opaqueness points to reduced cell content, although the reverse deduction does not hold.

An alkalinity giving a p_H of 8.1 to 8.4 has been so constant in our experience that it seems an unnecessary refinement except in research study and we do not yet know the significance of wider variations in reaction.

Fig. 1—Normal spermatozoa $\times 1,600$. The darker area at the cephalic base takes the blue nuclear stain, the cytoplasm red.

specimen may be said to be fertilizing or nonfertilizing, but we are striving to give the practical evidence by which semen deficiency may be estimated, errors in diagnosis reduced, and the necessity for improving the husband¹ as an important factor in the treatment of involuntary sterility recognized. The importance of semen subnormality as an element in the sterile union may not be determined by this evidence alone but by the facts elicited in a complementary study of all factors affecting fertility in the husband and wife.

The examination of the semen is best described in three steps: (1) collection of the specimen, (2) the gross or macroscopic investigation, (3) the microscopic study.

COLLECTING THE SPECIMEN

Because inquiry is so often made as to the best manner of obtaining the specimen and because its proper collection and delivery are the very foundation of

¹ Ma on L. W. Sterility with Reference to the Spermatozoa. Am. J. Obst. & Gynec. 17: 376 (March) 1929.

It has been pointed out to us also that the loss of carbon dioxide alters the body chemistry of the specimen

MICROSCOPIC EXAMINATION

Two specimens, one thick and one thin, are promptly prepared for microscopic examination. This is done by gently protecting a full drop and a fractional drop with cover glasses, the former permitting a gross impression of the density and motility of the cellular content, the latter allowing a preliminary study of individual cell morphology. In the thicker preparation, semen of relatively high fertility presents a field teeming with spermatozoa, many of which are rapidly propelled by fast-whipping tails. While universal cell activity would constitute the ideal, one usually notes in comparatively vigorous specimens that these fast travelers are colliding with a certain number of inactive (average 25 per cent) and a variable number of sluggish and impotent cells, which gradually sink toward the lower strata of the field. Familiarity with this picture under standard, dry, high-power magnification constitutes the measure by which motility is judged. It is a practical observation that a motile field though definitely subnormal is apt to convey a favorable impression on the inexperienced or occasional examiner, but reverse errors in interpretation are rarely made. In our experience the practical aspects of

Richness of cellular content, in terms of millions per cubic centimeter,² has been given emphasis by Macomber,³ Meeker and other workers as a further index of appraisal. While significant degrees of oligospermia are usually apparent to the experienced examiner on microscopic examination there is no verbal picture that will adequately provide such an index. It may

Fig 2—Spermatozoa with multiple nuclei and with caudal extremities in process of development. These cells each of which should produce four spermatozoa were liberated before division. Slightly reduced from a photomicrograph with a magnification of 1,200 diameters.

motility are that a large number of highly motile cells are essential to fertility, and when a specimen of normal quantity and rich cellular content shows 25 per cent or more of these dynamic cells a rating of relative fertility must be assumed unless strongly disproved by other indexes to be described. Such specimens usually meet other major requirements of fecundity.

Fig 3—Transitional cells divided but without complete evolution of component parts. Increased numbers of immature cells from the spermatocyte to the spermatozoon with protoplasmic deformity characterize one type of defective semen.

be said, however, that such specimens usually present other evidences of subnormality, such as lowered motility, increased number of abnormal cells, early crystal formation, and sometimes considerable indescribable debris. Such specimens may contain several round granular cells in each field. These may be leukocytes or cells from the seminiferous tubules. The larger granular cells are spermatocytes, there are usually four nuclei, which may be demonstrated by the staining process later described. Cell counts are probably modified by the amount of the seminal fluid and, while we agree with other observers that counts above 70,000,000 per cubic centimeter are found in fertile specimens, our experience would make us hesitate in setting a medium arbitrary count below which fertility is impossible. On the other hand, we have encountered a count as high as 112,000,000 in a highly defective specimen which was twice of less than 20 minims total quantity. This specimen promptly improved after treatment, and pregnancy followed.

Duration of motility is one essential to fecundation that can be easily determined. For this purpose the edge of the cover glass on the thicker smear should be protected by a layer of petrolatum or new smears made from hour to hour from the total specimen. A

² Thoroughly stirred semen diluted 1:20 with a solution of 4 parts of sodium bicarbonate and 1 part of phenol in distilled water. (Nose S. N. Critical Examination of the Semen in Relation to Sterility. Urol. & Cutan. Rev. 34:826 [Dec.] 1930.) In a white cell pipet should normally show from 14 to 25 spermatozoa to one great square that is sixteen small squares of the counting chamber.
³ Macomber, Donald and Saunders, M. B. The Spermatozoon Count Its Value, Diagnosis, Prognosis and Treatment of Sterility. New England J. Med. 200:981 (May 9) 1929.

normal specimen exhibits little cessation at the third hour after emission, and considerable cellular activity should be found at the fifth or sixth hour. Complete or considerable subsidence of motility within this limitation should be regarded as a further index of deficiency, but it should be noted that the few motile cells that were originally active in a highly defective specimen occasionally survive for many hours. Reciprocal studies⁴ between the direct male specimen and its behavior in the female secretions tend to indicate that duration is practically synonymous with early vigor of motility, but there may be exceptions to this rule.

ABNORMAL MORPHOLOGY

Defective semen may be caused by abnormalities in the seminal tract through which or in which the spermatozoa are conducted or retained, or by disturbance of the spermatogenic function. The former condition, due to chronic infection, sex exhaustion, or congestion with possible blockade, is characterized by reduction of sperm cell vitality or by lessening of the cellular or fluid constituents of the semen. These cases, we believe, constitute the group that respond to prostatic massage, heat and rest.

The latter condition, defective spermatogenesis, frequently occurs in men who give no evidence of local pathologic changes and who are classed as passable subjects by unbiased endocrinologic and medical consultants. The semen is occasionally characterized by complete lack of sperm cell production, but more frequently we encounter lesser degrees of sperm reduction with high percentages of abnormal cells (from 30 to 70 per cent), the product of incomplete evolution (fig 2). We believe that these cases, for which further remedies are so sorely needed, frequently arise from deficient gonad activation similar to that encountered in otherwise healthy women. The latter group of cases has been made the subject of special study by the junior author assisted by the hematology laboratories of the medical department of the New York Hospital. All maldevelopments of the spermatozoa with special regard to immaturity (figs 2-4) have been the chief topic of

Fig 4—Comma cell, distorted nucleus and deficient cytoplasm. Numerous in some highly defective semens. Less easily recognized in the wet specimen than the commoner known abnormalities.

this study rather than variation in the length of the sperm head, an index described by Moench⁵ which we have found difficult to adapt clinically to the human product.

In the course of our examination of seminal specimens, it was felt that there was an urgent need for

an improved staining process to define more clearly the exact morphology of the spermatozoon. Heretofore it was directed that the specimen was to be smeared on a slide and treated with heat, air or alcohol for fixation. The delicate cells were consequently distorted by dehydration and their contour materially falsified by shrinkage. Likewise the extracellular debris, purported to be partly removed by a chlorazene wash, still remained in sufficient quantity to obscure further the character of the spermatozoa.

After many trials with various agents it was found that Schaudinn's solution was ideal for the fixation process, for it not only preserved the normal morphology of the cells but also removed the objectionable debris. The next problem was to devise a balanced stain that would demonstrate all portions of the spermatozoon yet spare the chromophilic substance from over stain.

The following technic permits illustration of the head, midsection and tail of the sperm (fig 1)

A. Prepare thin cover slip smears as used in the preparation of blood for staining.

B. Fixation in Schaudinn's solution. 1. Immerse for one minute in 7 per cent solution of corrosive mercuric chloride, 2 parts, and absolute alcohol, 1 part.

2. Immerse for half a minute in 50 per cent alcohol.

3. Immerse for half a minute in distilled water, 3 ounce and tincture of iodine, 2 drops.

4. Wash in tap water.

C. Staining process. 1. Immerse for half a minute in aqueous solution of eosin 5 per cent.

2. Immerse for one minute in 50 per cent alcohol, 3 ounce and concentrated hydrochloric acid, 2 drops.

3. Wash in distilled water.

4. Immerse for two and one-half minutes in hematoxylin.

5. Immerse for one minute in distilled water, 3 ounces and glacial acetic acid 2 drops.

6. Wash in distilled water.

Dry and mount.

The importance of the stained specimens may be realized by the accompanying photomicrographs, taken with the aid of an oil immersion objective. The striking contrasts in size, shape and nuclear arrangement may be especially appreciated by the fact that all exposures are taken at the same magnification (1,600 diameters). The nuclei stain blue and the cytoplasm red, a feature unfortunately lost by black and white photography. These abnormal forms may possess motile facilities when they are observed in the wet specimen. On postcoital examination, however, they are rarely if ever found in the upper levels of cervical mucus and we consider them ineffectual for fertilization.

In appraising seminal specimens, we deduct the percentage of abnormal forms found from the total cell count. The resultant figure, when correlated with other data, is of great importance in the more accurate evaluation of the semen. For instance 40 per cent of inactive cells with 25 per cent abnormal forms would indicate more serious impairment and need for greater improvement in a specimen with a count of 60,000,000 or less than would obtain with a cell count of 100,000,000.

THE ROENTGEN DEMONSTRATION OF CALCIFIED CORONARY ARTERIES IN LIVING SUBJECTS

PAUL H WOSIKA, MD
AND
MERRILL C SOSMAN, MD
BOSTON

living subject For this reason we are presenting three cases in which calcified coronary arteries have been shown during life One of these cases came to autopsy and the pathologic examination confirmed the interpretations applied to these shadows seen roentgenoscopically and roentgenographically

CASE 1—E L a housewife, aged 67 entered the Peter Bent Brigham Hospital, Dec 2, 1933, complaining of precordial pain

Fig 2 (case 1)—Roentgenographic appearance of the heart after autopsy showing amount and distribution of calcification in the coronary arteries with arrows pointing to the same shadows shown in figure 1 The wire ring is around the aortic valve in which there is a single nodule of calcification

Fig 1 (case 1)—A fast film (exposure one-thirtieth second) showing 1 descending branch of right coronary artery 3 left coronary artery with typical parallel and segmental shadows

calcifications that have been shown roentgenographically, there is no record to our knowledge of calcified coronary arteries having been demonstrated in the

of about twelve years' duration The pain had become so severe that very slight exertion would precipitate an attack The distress was described as a sensation of "the chest being drawn together," and the pain radiated into the left side of the neck and down the left arm It was always relieved by glyceryl trinitrate The important physical changes were limited to the heart, which was slightly enlarged and over which an aortic systolic murmur could be heard On one occasion an aortic systolic thrill was palpable A diagnosis of angina pectoris and aortic stenosis was made by her physician, Dr S A Levine, and because of the incapacitating nature of her illness she was referred into the hospital for the relief of these symptoms by total thyroidectomy³

At fluoroscopy, December 5, the heart was noted to have a rapid, regular beat of fair amplitude There were visible small areas of calcification in the region of the coronary sulcus thought to be in the coronary arteries The slight cardiac enlargement was verified by a seven foot heart film There was no abnormality in the contour of the heart except for a tortuous aorta Speed films (fig 1) taken accurately through the area of calcification confirmed the fluoroscopic observation

Following thyroidectomy a typical attack of acute coronary thrombosis developed and the patient died At autopsy the mediastinal tissues together with the heart and lungs were removed in order to preserve, as far as possible, the ante-mortem relationships Stereoscopic films of the preparation showed marked calcification in the coronary arteries (fig 2) The left coronary artery had three main branches, all of which showed calcification extending almost to the apex of the heart The right coronary artery had a single branch, which was calcified The maximum calcification was at the point where the left coronary artery divided into the interventricular and left marginal branches There was also marked calcification

³ Total thyroidectomy was performed in cases 1 and 3 by Dr E C Cutler

Read before the New England Roentgen Ray Society Dec. 15 1933 From the Medical Clinic and the Department of Roentgenology of the Peter Bent Brigham Hospital

¹ Sosman M C and Wosika P H Calcification in Aortic and Mitral Valves with a Report of Twenty Three Cases Am J Roentgenol 30 328 1933

² Roesler H Roentgen Ray Interpretation of Cardiovascular Disease part III Modern Concepts of Cardiovascular Disease vol II November 1933

in the wall of the aorta, and a few irregular calcified nodules were present in the aortic valve. The latter was so slight that it was impossible to see radiographically despite the fact that its presence was suspected clinically.

The pathologic examination confirmed the fluoroscopic impression and roentgenograms.

CASE 2—P. B., a chauffeur, aged 67, entered the hospital, Jan. 30, 1933, complaining of jaundice of one week's duration. He had been well most of his life until eight years before admission, when he first noted substernal pain. The pain was gripping in character, was moderately severe, and radiated into the left shoulder and down the left arm. The number of attacks increased in severity through the succeeding years but these were always controlled by rest or glyceryl trinitrate. Physical examination showed that the area of cardiac dullness was increased, but nothing else abnormal was noted except moderate peripheral arteriosclerosis.

A gastro-intestinal series, February 3, was negative but during the fluoroscopic examination a linear area of calcification was discovered within the heart shadow. The calcified area was semilunar in shape, with the convexity directed upward, and was from 6 to 7 cm. in length. This shadow was in the region of the left coronary sulcus quite close to the heart surface. There was only slight movement of this shadow toward the apex with systole, in contradistinction to the dancing movement previously described for the shadows cast by calcified valves. The shadow was diagnosed as a calcified coronary artery because of its position in the coronary sulcus near the heart surface, its linear convex shape and its limited motion during systole. It was further demonstrated on speed films (fig. 3).

The jaundice cleared and the patient was discharged, February 16. He continues in his limited activities and controls the angina pectoris with glyceryl trinitrate.

CASE 3—A. P., a truck driver, aged 60, who reentered the hospital, Nov. 7, 1933, had been a patient in several departments

was examined roentgenographically, Feb. 17, 1931, Sept. 10, 1931, and Sept. 19, 1933. On each of these occasions the heart was found to be well within normal limits and normal in contour. Fluoroscopic examinations were reported to give negative results. The heart was seen to beat regularly and with good amplitude. Although there was a large functional element in the patient's condition, the incapacitating angina pectoris continued and on Sept. 21, 1933, a total thyroidectomy was performed successfully, completely relieving the substernal pain.

Fig. 4 (case 3)—A fast film (exposure one twentieth second) showing calcified right coronary artery at 1, costal cartilages at 2 and left coronary artery at 3.

Two months after thyroidectomy the roentgenoscopic appearance changed. November 16 the heart was found to be enlarged. The total width was 2 cm. greater than on previous examinations. Fluoroscopy showed a regular beat of fair amplitude. There was a linear segmental shadow apparently cast by calcium deposited just under the pericardium on the left border. This was seen best in the right anterior oblique position. Another shadow with the same linear segmental appearance was seen to curve downward and to the right. These shadows in all probability represented calcified right and left coronary arteries and were clearly shown on films taken through those areas (fig. 4).

COMMENT

It should be remembered that not every small fleck of calcium in the coronary arteries can be visualized roentgenographically. A fairly large amount of calcium is required to interrupt enough rays to cast a shadow that can be recognized. Judging, however, from the numerous instances of massive calcification of the coronary arteries noted at the autopsy table, the roentgen diagnosis during life should be a common one.

It is well to emphasize again that these small calcifications in the heart shadow are seen only when they are searched for. The observer, when his eyes are properly accommodated, should look through the cardiac shadow on fluoroscopic examination rather than simply at the movements of the heart borders. The patient should be rotated in all directions. Closing one's eyes for a few moments often rests them and brings out the dark shadows more clearly. That this intracardiac calcification is seen only when looked for is well exemplified by case 3. This patient had been examined fluoroscopically on three occasions and only two months had elapsed between the discovery of the calcified vessels and the

Fig. 3 (case 2)—A fast film (exposure one twentieth second) showing the arched semilunar shadow of the calcified left coronary artery at 3 and a calcified costal cartilage at 2.

for more than two years, during which time his major complaint had been substernal pain. The pain occurred in attacks as a result of mild exercise and radiated into the left shoulder and left arm. It was usually relieved by glyceryl trinitrate but on several occasions it was persistent and occlusion of the coronary artery was suspected. This diagnosis could not be substantiated. Physical examination of the heart was negative. There were no thrills, murmurs or irregularities of rhythm. There was moderate peripheral arteriosclerosis. The patient

previous examination. The amount of calcium present could not possibly have developed in those two months, regardless of the increased heart size.

Fluoroscopically, as one would expect, the calcium deposit is seen in the coronary sulcus. This is high on the left border of the heart and is seen best in the right anterior oblique position. The shadow cast is quite close to the heart border, apparently just under the pericardium. There is a slight movement during systole which is similar to that of the heart edge directly over the deposit. The shadows are to be differentiated from calcification in the valves by their location. Valvular calcifications are usually found by locating the auriculo-ventricular groove on the left border and searching through the heart shadow downward, inward and medially at an angle of 45 degrees. The movement of the valvular calcifications is also characteristic in that they move toward the apex with systole and occasionally intrinsic movements of the valves may be seen as well. This imparts the dancing motion that has been described previously.⁴

The appearance of the calcified arteries on films also is characteristic. The shadows appear linear and segmental and are curved corresponding to the course of the artery. The linear shadows also appear double on the speed films and parallel in places as if one were seeing the walls of the artery. In our three cases the arrangement of calcium in no way resembles the structureless mass of calcium seen in the valves.

Other areas to be differentiated from the calcified coronary arteries are (1) pericardial calcification, (2) calcified costal cartilages, (3) bronchi behind the heart and (4) calcified lymph nodes or nodules.

1. Calcified areas in the pericardium are parallel to the heart surface in at least one view. They move with the heart surface but slightly, as a rule, as visible pulsations are considerably diminished by the thickened and adherent pericardium. They are most commonly found where the heart is in contact with the diaphragm, more on the right side, but may frequently be found in the coronary sulcus. Here the fast films are of value, as this calcification is more solid, often branching and sometimes intercommunicating, forming a network. One does not see the interrupted segments parallel to each other so characteristic of the calcified arteries.

2. The calcified costal cartilages run in an entirely different direction from the calcified arteries and are usually smoother, sharper and denser. They are not confusing at fluoroscopy but may be so on the films. The typical appearance of such a calcified cartilage is shown at 2 in figure 3 and 2 in figure 4.

3. The bronchi behind the heart are not as dense or as opaque as the calcified arteries and they, too, run in a different direction. They may, however, parallel the descending branch of the right coronary artery but they are easily recognizable and should not cause much, if any, confusion. They do not complicate the fluoroscopic picture.

4. Calcified glands and nodules in the lungs or mediastinum are readily differentiated both fluoroscopically and radiographically by their more dense solid and rounded appearance and should not cause any difficulty in interpretation.

It is interesting that the three patients suffered from angina pectoris. We feel that the severe grade of coronary sclerosis demonstrated is of interest in relation

to this condition, and it is possible that the demonstration of such calcification may be of aid in the determination of the etiology of angina pectoris in certain cases.

FAMILIAL NEUROTROPHIC OSSEOUS ATROPHY

A FAMILIAL NEUROTROPHIC CONDITION OF THE FEET WITH ANESTHESIA AND LOSS OF BONE

E. MAURICE SMITH, M.D.
MOUNT VERNON, ILL.

An unusual clinical condition, which has not permitted definite classification, has been observed in two generations of a family, and there is definite history of

Fig 1—Lesions in case 1

the same disease in an earlier generation, making three generations in which the condition has appeared.

FAMILY HISTORY

The father (first generation) of the three men (second generation) who now have the condition described died many years ago but is said by the sons to have had ulceration of the feet with anesthesia and with loss of bone similar to that which afflicts the three sons. This man is reported to have had a brother who was afflicted in the same manner. None of the five daughters of the man first mentioned gave a history of a similar condition. The father was married twice. One of the patients in the series to be described in the second generation was born of the first union, and two of the second union. Otherwise the family history is not important save that all members of the family group considered have been born and raised in southern Illinois and have always lived there or elsewhere in the northern part of the United States. The condition to be described is essentially an ulceration of the soles of the feet associated with anesthesia and destruction of bone. It is familiar in occurrence and so far as can be ascertained appears to have been confined to males.

⁴ The technique and the literature on this subject may be found in the previous report.

CASES IN SECOND GENERATION

CASE 1—C F, Sr, aged 53, a farmer, worked at times in industrial establishments. There is at present a crater shaped ulcer about 3 by 5 cm in diameter on the under surface of the left foot just behind the first and second toes. To the right and left and slightly behind this large ulcer are two much smaller ulcers, as will be noted in figure 1. The ulcers are

Fig 2—Anterior posterior view of right and left feet in case 1 showing a loss of several phalanges, marked hypertrophic changes, spur absorption of small toes of both feet fusion of metatarsals of the left foot, no calcification and apparently no osteoporosis

red, granulating, and surrounded by a heavy callus. There is a profuse discharge with a slight odor. The patient states that the large ulcer developed after a burn of the sole, which occurred ten or twelve years ago while he was working in a foundry. He states that pieces of bone are discharged from this ulcerating area. For the past twenty years, at intervals,

Fig 3—Anterior posterior view of feet in case 4 revealing a loss of the phalanges and a part of the metatarsal of the left foot neurotrophic destruction of the joint of the left fifth toe entire loss of the fifth toe and a part of the metatarsal with apparently no atrophy, decalcification or osteoporosis

there has been ulceration of the toes of both feet with destruction of bone, which can be observed in roentgenograms. Complete healing of the toes occurs after ulceration, but anesthesia remains. The ulceration on the plantar surface of the foot never has completely healed. There is an absence of the sense of touch and pain throughout the sole and the inner aspect of

the dorsum of the left foot. There is a similar area of loss of sensation on the right foot. These ulcers are indurated, and destruction of tissue is much greater than appears on the surface. The ulcers are quite painless, the patient walking about without discomfort. Recently the patient, while working in the timber, cut through the left shoe, inflicting a wound on the foot, but was unaware of having injured the foot until he returned home, removed his shoe and found it filled with blood. At intervals of about three months the patient has a high fever which lasts from twenty-four to forty-eight hours, with mild delirium, swelling of the feet, and glandular enlargements.

CASE 2—A F, aged 32, a half brother of patient 1, is reported to have had the condition since the age of 19 years, at which time blisters developed on the toes and soles of both feet. These blisters healed after discharge of bone, excepting an ulcer on one foot. There was at the time of ulceration pronounced loss of sensation on the dorsum of the right foot and slight loss of sensation on the left foot.

CASE 3—E F, aged 34, a brother of patient 2 and a half brother of patient 1, had blisters on the toes of both feet at approximately the age of 14, with discharge of pus and pieces of bone. At one time he had a positive Wassermann reaction and was placed on antisyphilitic treatment, without material change in his condition. At present there is ulceration and anesthesia of both feet.

Fig 4—Posterior anterior view of feet in case 5 showing neurotrophic destruction of the tarsometatarsal joint of the left great toe complete absorption of the terminal and middle phalanges of the fourth toe loss of terminal phalanges of the fifth toe with apparently no rarification or atrophy of bone

The data on cases 2 and 3 were furnished me by a professional colleague who has seen these cases recently in another state and who kindly furnished the information.

CASES IN THE THIRD GENERATION

These patients are sons of patient 1. There are two sons and three daughters in this generation who are free from the disease.

CASE 4—H F, aged 23, presented a history covering a period of five or six years. An ulcer developed after a tack had been accidentally run into the foot without causing pain. This small wound developed into an ulcer, which never has completely healed. There is at present an ulcer, perhaps 1 cm. in diameter, on the inner aspect of the sole of the right foot just behind the great toe. There are anesthesia and analgesia over an area about 30 mm in diameter around a similar ulcer on the left foot, and an area of loss of sensation on the dorsal aspect of the fourth toe of the left foot. There is some loss of sensation noted on the dorsal aspect of all toes of the right foot. There has been an amputation of the fifth toe, this amputation having been performed without an anesthetic.

There has been also an amputation of the fourth toe of the left foot (a small amount of anesthetic was used for this amputation) The patient sheds his toenails every two or three months There is also ulceration of the toes at intervals

CASE 5—C F, Jr, aged 18, shows destruction of the bone at the tarsometatarsal joint of the left great toe, and an absence

surface Shivers of bone have been discharged from the ulcer on the foot and from several of the toes, always painlessly The only area of anesthesia is one extending about 4 cm around and bordering the ulcer on the left foot The boy is an all-round athlete, playing basketball and football on the high school team without discomfort

COMMENT

Microscopic examination of nasal smears and biopsy material from the lesions on the feet has been negative for acid-fast bacilli The Wassermann reaction is negative in all cases excepting case 3, as noted Many diagnoses have been suggested and considered, none of which seem satisfactory Syphilis, tuberculosis and syringomyelia are readily eliminated on clinical grounds Leprosy has been given serious consideration but is to be excluded on account of the absence of manifestations elsewhere than on the feet and the uniformity of the type of manifestations in all members of the group The patients were seen by a consultant with a large experience in leprosy, who ruled out that condition However, he stated that any one of the cases considered alone would justify a strong suspicion of leprosy

1001½ Broadway

Fig 5—Lesions in case 6

of the distal phalanx of the third toe and the second and third phalanges of the fifth toe There is also a large ulcer on the dorsal side of the second toe, with destruction of the first phalangeal joint of the third toe The condition is of eighteen months standing

Fig 6—Anterior posterior view in case 6 revealing a neurotrophic destruction of the first joint of the left foot loss of the distal and middle phalanges of the fourth toe and no marked atrophy or decalcification

CASE 6—S T, aged 16 years has had the condition for about three years The ulcer covers an area of 5 by 2 cm on the plantar surface of the left great toe extending downward to the first phalanx of the great toe. On the right foot the first and second toes show superficial ulcers on the plantar

SARCOMA OF CHEEK FOLLOWING TRICHO X-RAY TREATMENT FOR HAIR ON FACE

REPORT OF CASE

IRA I KAPLAN, MD

Director New York City Cancer Institute Visiting Radiation
Therapist Bellevue Hospital

NEW YORK

The early enthusiasm that attended the discovery of the x-rays gave rise to their employment by methods that bore no regard to inherent physical and biologic factors associated with this form of energy This disregard of these biologic factors led to many unfortunate reactions and sequelae both on the person of the x-ray operator himself and on the patient Marcuse in 1896, according to Ewing,¹ made the first formal report of this condition, and Kienbock, cited by Ewing, in 1900 described in detail this x-ray dermatitis

Among the biologic reactions early recognized was that the x-rays caused epilation It was found that this agent, when properly employed and applied only within certain fixed limits established by physical and biologic measurements, produced this epilatory result without destructive effect on the tissues to which x-rays are administered

The early advocates of x-rays suggested their use as a panacea for many skin conditions, including hirsuties facialis The obvious simplicity with which epilation was effected by the application of x-rays quickly gave them a place in the armamentarium of the dermatologist MacKee,² however, warned against the careless use of x-rays for this purpose, because careful observers have learned that overexposure or oft repeated exposure of the skin to x-rays produced a thickening of the skin, with telangiectasis, keratosis and at times definite ulceration necrosis According to Matas³ these untoward sequelae may appear many

months and even years after the first application of x-rays has been given

That malignant changes in the skin and adjacent tissues have followed excessive applications to portions of the body has been definitely demonstrated. Porter⁴ in 1909 reported forty-seven cases of skin injury due

degenerative changes in cases coming under these observations. Pfahler,⁷ reporting on the occurrence of keratotic and malignant changes in irradiated skin, believes that most such malignant changes are of the epitheliomatous type, which is in accordance with the observations of other workers in this field. Sarcomas following x-ray injury of the skin are rare.

Stout states that sarcoma followed intensive roentgen therapy of lupus and other skin lesions and according to Harbitz quoted by Stout the x-rays are a definite etiologic factor in the formation of some sarcoma. Two cases of sarcoma of the skin after roentgen irradiation are reported by Bohmer.⁸ I have seen many cases of x-ray burn and malignancy of the carcinomatous type at the New York City Cancer Hospital but the case reported here is the first one of sarcoma seen.

Fig 1—Telangiectasia and scarring of left cheek eight and one half years following Tricho x-ray treatment for hair on face.

Fig 2—Fibrosarcoma on right cheek of the patient

to x-rays, forty-one of which proved to be malignant. Wolbach⁵ states that malignant changes in the skin following irradiation is not a sudden occurrence but is gradually acquired over a period of years. He describes in detail the histologic changes taking place in such lesions. MacKee, Stout⁶ and others report such

Fig 3—Telangiectasia of patient's face

Until recently, the absence of any governmental restrictions relating to who should be permitted to use x-ray apparatus suggested to many lay persons, with little or no knowledge of the physical and biologic factors of x-rays, the employment of this modality in the treatment of various superficial conditions and these beauty specialists adopted this method for treating hirsuties facialis.

One such notorious group was the Tricho Company, which advertised hair removal by x-rays at moderate fees. Its methods were exposed in THE JOURNAL,⁹ and the serious results of such treatment began to be reported in the literature by Lane¹⁰ and others.

The case here described is one of definite malignant degeneration of the skin and subjacent tissues eight and one-half years after roentgen treatment for hair removal by the Tricho method

REPORT OF CASE

J N, a woman, aged 28, single a milliner, was admitted to the New York City Cancer Institute Aug 3, 1933, because of a growth on the right cheek. In 1926, having an excessive quantity of black hair on her face, she sought treatment at the Tricho Institute. There she received two roentgen treatments a week until a total of twenty treatments had been given to each side of the face. Epilation was effected at the end of the treatments. Later she noticed some gradual changes in the skin, such as reddening and whitening but thought nothing of it. About two years before admission, however, she perceived what she termed a growth developing on the right cheek. In the spring of 1933 she noted, after exposing her face to the sun, that there was a steady increase in the size of the tumor mass and came to the Cancer Institute on the advice of a physician.

Examination on admittance showed marked telangiectasis and scarring of both sides of the face, the upper lip and the chin. On the right cheek there was an irregular granular, strawberry red tumor mass measuring 1 by 2 inches (2.5 by 5 cm) and three eighths inches (1 cm) high, covered by an apparently infected dirty scab. The mass was firmly adherent to the underlying structures of the cheek.

A diagnosis of epithelioma on the basis of an x-ray burn was made, and because of the infection present the patient was advised to apply wet dressings to the cheek, following which radium therapy was to be employed to control the malignancy.

The patient left the clinic and did not return until one month later, when the lesion appeared to have increased in

Examination of the tumor mass by Dr Sala, the pathologist of the institute, proved it to be spindle cell sarcoma.

At the present time the lesion is not completely healed.

CONCLUSIONS

Repeated roentgen treatments may cause destructive lesions of the skin. Because of its potential danger,

Fig 5—Section of spindle cell sarcoma under high power

Fig 4—Section of spindle cell sarcoma under low power

irradiation should be employed only by those properly qualified by special training and experience.

These destructive changes may occur many months or even years after treatment.

Malignant changes may occur following necrosis in an overirradiated skin area.

Removal of hair by x-rays is fraught with danger.

In the case reported sarcomatous degeneration followed repeated treatments with x-rays for hair on the face, applied by Tricho, a commercial beauty parlor

55 East Eighth-Sixth Street

Borborygmi—There are borborygmi which matter and borborygmi which do not. The commonest are the almost musical borborygmi of the nervous maid waiting at table. There is another curious type of rhythmical bubbling in the stomach, synchronous with the respirations, which occurs in nervous enteroptotic women who have acquired a faulty habit of abdominal breathing. These are gastric in origin. But there are also intestinal borborygmi of grave import in chronic obstruction, which synchronize with peristaltic movements subterranean in quality and recurring at more or less regular intervals. Without putting the ear to the abdominal wall, they may be readily located in the bowel. Finally, there are sounds which I would characterize as "hollow tinklings," which may be heard in cases of paralytic distention of the gut, or again in chronic intestinal obstruction. The sense of hearing, like the sense of sight, can only be trained and put to better use by paying attention and by deeming nothing so trivial as to be allowed to escape your notice.—Ryle J A. The Training and Use of the Senses in Clinical Work, *Guy's Hosp Gaz* 47:421 (Oct 28) 1933.

size. She was admitted to the hospital and a biopsy of the tumor mass was taken and a radium pack applied. A dose of 1000 millicurie hours was given over a period of several days, and the patient discharged from the hospital.

The report of the biopsy was "fibroblastic granulation tissue."

The lesion failed to heal and one month after the radium treatment October 16 the patient was readmitted to the hospital and the whole lesion removed by operation.

DELAYED APPEARANCE OF DEFORMITY IN VERTEBRAL BODY FRACTURES

O O FEASTER, M.D.

ST. PETERSBURG, FLA.

Low back pain constitutes a rather important condition in medical practice, and it is one for which the physician has often been able to do very little. Frequently this is because a compression fracture of a vertebral body has been undiagnosed. There may never have been a roentgen study of the case to account for nonrecognition, or roentgenograms may have been made properly and promptly after the injury but no abnormality was discovered.

It is my purpose in this communication to call attention to a class of spinal injuries—compression fractures of the vertebral bodies—which show no evidence of fracture deformity when roentgenograms are made immediately after the injury but on subsequent study ten days or more later do show a recognizable deformity in the lateral silhouette.

Having observed this sequence in three cases, I have made it a routine procedure in reporting a normal spine, following trauma, however slight, to request the referring physician to return the patient in from ten days to three weeks for a recheck should discomfort or disability continue, for there are instances in which compression fractures of the vertebral bodies show after an interval that are not demonstrable immediately after the injury.

The reason which seems logical in explanation of this observation is that the vertebral body is cancellous bone with the rather poorly constituted blood supply common

Fig. 1—Appearance twenty four hours after injury, no evidence of fracture.

to that type of structure. The trauma, although disturbing bone homogeneity, with resultant nutritional interference, is not sufficient to distort body outline. Subsequent pressure on this disturbed body by weight bearing, as in walking, or by muscular pull or flexing of the spine if recumbent, serves to deform the silhouette.

From St. Anthony's Hospital

The accompanying illustrations show examples of this type of case. Figure 1 is from a film made twenty-four hours after a slight fall by a woman, aged 80. The first lumbar vertebra shows no disturbance. The discomfort, which was chiefly pelvic, continued, and after undue delay the patient was returned for the film from which figure 2 was made. This shows a

Fig. 2—Appearance twenty four days later, definite compression fracture of the first lumbar vertebra.

definite wedging and a break in the continuity of the more compact bone of the anterior margin of the silhouette.

It is probable that many, if not all, of the cases of so-called Kummell's disease belong to this class of injury, that is, compression fractures not recognized at the time of injury and probably not studied again until the diagnosis of Kummell's disease is made. It is seriously doubted that Kummell's disease should be considered a disease entity.

A most striking thing in the study of a number of reports of vertebral body compression fractures is the surprisingly slight degree of trauma that may be responsible. A degree of wedging that is seldom seen occurred in a heavy woman, aged 60, as the result of a five or six inch drop when an earthenware chamber on which she was sitting split. Another with marked deformity resulted from the impact caused by an automobile, on the rear seat of which the patient sat, crossing a "dip" in the street. Several have been from missteps of from eight inches to three feet.

One should always bear in mind that the injury is frequently at a much higher level than the pain. Two patients have been seen, each with both the eleventh dorsal and the first lumbar vertebral bodies fractured, of whom the surgeon requested a study of the sacroiliac region, and quite naturally, for there was no discomfort elsewhere.

It is, of course, superfluous to mention that no roentgen examination of the spine is complete that does not include a lateral view, in fact, this is usually the only film of definite value.

CONCLUSIONS

1. There are compression fractures of the vertebral bodies which are not apparent immediately after injury but which may be demonstrated some days later.

- 2 Reexamination, after an interval of from ten days to three weeks, should be made in all cases in which discomfort persists
- 3 This type of case probably constitutes the so-called Kummell's disease. It is doubtful whether Kummell's disease is an entity
- 4 Seemingly very slight direct and indirect violence may be responsible for major compression fractures of vertebrae
- 5 The lesion may exist from five to seven vertebrae above the site of pain
- 6 A lateral view of the bodies is absolutely essential

ROUTINE USE OF NEOSKIODAN IN SUSPECTED INJURIES TO THE GENITO-URINARY TRACT

CHARLES MORGAN McKENNA, M.D.

Head of the Department of Urology, University of Illinois College of Medicine
CHICAGO

My purpose in this paper is to point out what a valuable asset excretory urography is in making an early diagnosis in patients suffering with trauma of the genito-urinary tract. It is valuable not only in a positive way but in a negative way as well. Every surgeon recognizes the importance of early diagnosis of trauma, or what is commonly known as internal injuries. Many patients have been lost because of watchful waiting, and many patients have been operated on who could have made a recovery without surgical intervention. This is true not only of trauma but of other pathologic conditions as well. One usually assumes that a person who has been injured was normal until the time of the injury. I have found many times in my observations that a number of these patients had a pathologic entity before the trauma took place. This pathologic condition, observed at the time of the injury, makes the picture more difficult. The problem at this time is to determine whether the pathologic condition existed before the trauma or whether the trauma was the cause of the condition. In passing I cannot help but point out and emphasize the value of excretory urography in patients who have not been injured. It is particularly valuable in tumors, stones, anomalies, tuberculosis and other advanced infections of the kidney. I hope to be able to show the value of excretory urography in tumors of the kidney. In some of those cases a negative result is obtained on the affected side, which when interpreted, means the pathologic side. This is true also in far advanced infections of the kidney and many times it points the way for further investigation in renal tuberculosis.

This paper would not be complete without mentioning the extreme value of excretory urography and the indication for its use in children. This is true not only in trauma but also in many suspected pathologic conditions of the genito-urinary tract. The ease with which it is administered should be emphasized. Of course the size of the dose in children is always much less than that in adults.

We have found both in Cook County Hospital and in the Research Hospital many cases diagnosed that would otherwise have been discharged from the hos-

pital without our even knowing that the patient had any pathologic condition of the genito-urinary tract.

The subject of trauma should be a chapter in itself. In industrial surgery it is very important to know whether the patient is suffering with an injury to the genito-urinary tract or whether that tract can be ruled out, so it is easy enough to see what an important part excretory urography would play in that type of case. For instance, a patient has received an injury and it is difficult to tell whether the injury involves the genito-urinary tract or the organs of the peritoneal cavity. The administration of skiodan will rule the genito-urinary tract either negative or positive and will help the surgeon that much in making an immediate diagnosis. After all, that is the entire point of this paper—immediate diagnosis.

In the past, one had to depend entirely on the history of the injury plus the physical examination. In many instances external trauma is not present. Blood in the urine is the most common observation. Shock may or may not be present.

I believe that the value of excretion urography is an adjunct in completing the diagnosis. I am of the opinion, however, that this procedure, when indicated, taking into consideration shock, gives valuable information as to the immediate procedure in management.

In this paper I shall consider the genito-urinary tract in the following order: trauma of the kidney, ureter, bladder and urethra. Conservatism should be the password in relation to trauma of the kidney. Three of the most important factors should be taken into consideration: first, the general condition of the patient, second, the extent of the injury, and, third, the element of time.

The question of shock, which is a most important one, will be managed in the same way as it would be in any patient suffering from a similar condition. At this point I would like to emphasize that the use of intravenous urography is left to the discretion of the surgeon in charge of the injured patient.

The next question of importance is to find out the extent of the injury to the kidney. Is the rupture within the kidney itself, has it extended through the true capsule or has it invaded the peritoneal cavity? In other words, it is imperative to know whether one is dealing with an extracapsular condition or an intraperitoneal tear.

The foregoing statements are of the utmost importance, since the management depends so much on the interpretation of this condition. I believe that excretion urography at this point is of the greatest advantage. If the rent is extraperitoneal and the amount of extravasation is small, I advise watchful waiting and, again, repetition of the first operation, viz., the making of a pyelogram to find out whether or not the extravasation has increased in size. This is most important because so much depends on whether or not the hemorrhage is entirely within the kidney and is draining into the bladder. In other words, the question of decision plays an important role in all cases of traumatic kidney.

Other factors must not be forgotten, such as blood pressure, blood counts and hemoglobin, all of which add to the information desired in this class of case. So again I want to emphasize the question of time.

First as stated before, conservatism should not be forgotten. If the rent is intraperitoneal, immediate surgery is indicated provided the general condition permits. In many of these cases the kidney may be

detached from its pedicle and rest in the peritoneal cavity or in the perinephric space without any apparent injury to the patient externally

CASE 1—A boy, aged 13 years, entered the hospital, Jan. 1, 1930, with a severe pain in the right side of the back. He had sustained an injury while sliding down a hill on a low sled, which was diverted and ran into a tree. He was picked up

Fig. 1—Ruptured kidney and partially ruptured ureter shown by excretory urography

unconscious and taken home and remained in shock for an hour. There were no marks or abrasions on the skin nor any symptoms of external injury. On first urination macroscopic blood was seen in the urine. He was treated by a local physician for about a day and a half. The urine contained much blood at times and at other times appeared clear. On entrance to the hospital he had the appearance of being very sick, very anemic, with the conjunctiva perfectly white, the finger nails on pressure showed no change, hemoglobin was 50 per cent. Slodian was given. He was given a blood transfusion and taken

to the operation room, where the injured kidney was removed. On opening the perinephric space I was confronted with a large hematoma. After the hematoma was removed the kidney proper was examined which showed the kidney to be ruptured and appeared to be broken in a transverse position. When the forceps was put on a clot was disturbed and I encountered a hemorrhage momentarily. This was controlled by the application of the hand to the renal artery, and I might add that a hemorrhage from the renal artery can best be controlled by engaging the vessel between the thumb and the index finger. This was held until forceps engaged the vessel and a ligature was applied. The operation was completed in the routine way. The patient made an uneventful recovery.

The second case was similar to the one just reported other than that the patient was a girl.

CASE 2—A girl, aged about 14 years, sustained an injury while running and was pushed into a projection of timber on the playground. She likewise was treated two or three days before being sent to the hospital. She had about the same pathologic condition as patient 1. A diagnosis was made by using excretory urography, which immediately told that there was a ruptured kidney. This patient, like patient 1, had no external marks of trauma, and was sent to the general surgical section because of the pain in the abdomen. She had all the appearance of a patient suffering with a disturbance in the peritoneal cavity and had been under observation before she was sent to the department of genito-urinary surgery. Diagnosis was quickly made and surgical intervention employed at once. She also had a rupture of the upper portion of the ureter.

I mention these cases as examples of the value of excretory urography in trauma of the genito-urinary tract. It so happened that in both cases the pathologic changes of the kidney were so great that removal of the organ was necessary. I have seen a number of cases in which the kidney was sutured after the removal

of clots and the patient made an uneventful recovery. A close examination of the kidney is therefore important regardless of how much blood or how many blood clots are in the perinephric space before it is determined whether nephrectomy is indicated.

I believe that in all cases of intraperitoneal tear the kidney should be immediately removed, whether or not it is partially detached. Of course, it should always be removed when it is totally detached.¹

The big problem is in the class of cases in which the hemorrhage continues for some days. When the injury is confined to the kidney, the problem is to decide whether surgical intervention is the best procedure or whether the patient should be allowed to bleed with the hope that a hematoma will form which will prevent further hemorrhage. I might add that in many cases while the hemorrhage ceases and the urine becomes clear, considerable pathologic change will develop. In three cases at Cook County Hospital in later years a complete atrophy of the kidney was observed. In one case a giant hydronephrosis appeared.

When hemorrhage is extracapsular, I advise the removal of all clots of blood and a careful examination of the kidney. By so doing one is able many times to save the kidney, which is the second consideration in the management of all these cases. I do not believe that in every case in which there is a rupture of the kidney and in which a large hematoma is present a nephrectomy is indicated. I believe that the kidney can undergo a great deal of insult and yet, when properly managed will recover. So as stated, if the clots and the hematoma are removed the bleeding points are

Fig. 2—Ruptured bladder revealed by injecting a contrast fluid into the bladder

sutured and a drain is introduced in the prekidney space, the patient will make a good recovery, and a good functioning kidney will be the happy result. However, there is one point that I should like to make, i. e., the introduction of paraffin catheters for the class of case

¹ In a case in which one kidney was found in the peritoneal cavity the patient died following operation. In another case due to a bullet wound in which the kidney was entirely detached the patient made an uneventful recovery.

in which the injury is within the kidney and no hematoma appears. By so doing pathologic changes of the kidney due to pressure necrosis may be entirely avoided.

In all cases of trauma of the kidney a flat roentgenogram should be made to determine the condition of the kidney on the opposite side. In all kidney surgery this should be done.

Rupture of the ureter may be divided into two general headings. Is it a complete or an incomplete tear of the ureter? The management in this group will be the introduction of a ureteral catheter at the time of injury in order that a continuity of the ureter may be present, which is easily done with a catheter in situ. One or two sutures may be employed. In many cases the catheter itself will suffice. By so doing a drainage has been established and the regeneration of the ureter will follow. In trauma of the urinary bladder the only question to decide is whether the tear is intraperitoneal or extraperitoneal. This, too, is well described with the use of excretion urography. I believe that all the other methods heretofore employed, such as the Vaughan-Rudnick test, the use of injection of fluid, which I heartily oppose, and the use of skiodan will tell exactly where the rent is and the extent of the extravasation.

In all cases of intraperitoneal tear, an abdominal incision is done as a routine, and repair of the tear in the bladder is drained to the peritoneal cavity, and the introduction of a retention catheter is the method advised. If I am dealing with an extraperitoneal condition I repair the bladder, institute drainage in the prevesical space and use a retention catheter.

There is a considerable amount of difference of opinion as to this procedure. The industrial surgeon usually advises the use of a retention catheter and takes a chance as to the recovery. This, of course, depends altogether on the condition of the urine whether one is dealing with an infected or an uninfected urine. Slough may take place with a superficial urinary extravasation.

The question of the urethral rupture is one that has caused an endless chain of argument. I believe that the most important factor is to establish immediate drainage through the urethra and, when possible, to do a suprapubic cystotomy and a retrograde sound using the Davis method of two sounds, one through the meatus and the other through the bladder, thereby introducing a retention catheter.

The hemorrhage in the perineum due to trauma will usually take care of itself after the introduction of a large catheter but if a hematoma should appear it is quite simple to open it and drain it. However, when the severed ends of the urethra are not intact it is easier to approximate the two ends if a urethral catheter has been introduced by the method previously mentioned. In other words the urethra now contains a splint by virtue of the catheter being in place. This simplifies the method of doing an end-to-end anastomosis of the urethra. It is not necessary to make this anastomosis watertight. I have modified the Davis sounds so that they are a little more adaptable to the case (fig. 2).

Much credit should be given to George C. Davis (Chicago) for devising this method of using two sounds in managing a ruptured urethra.

CONCLUSIONS

1. Excretory urography is of value in early diagnosis of trauma of the urogenital tract.

2. It is also of value in early surgical intervention when indicated.

3. The question of shock and time is an important factor.

4. A ruptured kidney is not always an indication for nephrectomy. In many cases the clots may be removed and the kidney sutured with good results.

5. The management of a ureteral tear is accomplished by doing a retrograde catheterization and screwing this catheter into one introduced from below.

6. Excretory urography in rupture of the bladder will show whether one is dealing with an intraperitoneal or an extraperitoneal tear.

7. In rupture of the urethra it is important to use two interlocking sounds, one introduced from the bladder through a suprapubic cystotomy and the other through the meatus, thus establishing coaptation of the severed ends of the urethra and drainage.

8. There is no place in surgery in which judgment and common sense is such an asset as it is in traumatic surgery.

25 East Washington Street

ABSTRACT OF DISCUSSION

DR. G. H. EWELL, Madison, Wis.: I am in accord with Dr. McKenna's views regarding the value of intravenous urography in traumatic injury to the urinary tract. What effect will the associated shock and the actual trauma to the kidney itself have on its function and its ability to excrete the dye? Dr. McKenna mentioned this point but did not say how soon after injury the cases in his series were studied. Dr. Zwick has shown that temporary inhibition of kidney function relative to its power to excrete the dye does occur. In the two cases that I saw, six hours had elapsed before intravenous urography was done. In both cases there was apparently no disturbance in the power to excrete the dye. In cases of traumatic injury of the kidney there is always an associated paralytic ileus and therefore considerable obscuring of the x-ray films by gas. I therefore find it necessary to make many exposures in order to get a composite picture of the urinary tract. Serial pyelograms, as suggested by Dr. Moore, would probably be a much more satisfactory procedure. I am sorry to disagree with Dr. Wesson concerning the value of intravenous urography in these cases as I am of the opinion that it represents one of its most valuable uses so far as diagnosis is concerned. However, the surgical management of such cases must depend on the clinical observations.

DR. MOSES SWICK, New York: I think it necessary to emphasize that all accident wards in hospitals should make it a rule to call in a urologist in a consulting capacity. The importance of proper diagnosis is based on various aspects. One, the trauma to the kidney is capable of producing functional damage and permanent damage as a result of extravasation. Furthermore, urography can be used to assist in the study of the secretions of the various portions and to show what processes are taking place in the kidney as to whether there is return of function or not. Similarly with injuries to the ureter and bladder these may also react on the kidney and produce functional inhibition.

DR. A. I. FOLSON, Dallas, Texas: The technic that Dr. McKenna showed is very important in handling ruptured traumatized or severed ureters. I feel that sutures should not be taken in them. It is sufficient to splint the ureter with a catheter and it is surprising what it will do. Dr. McKenna's method of invaginating these ureters and making it a closed operation is an excellent procedure.

DR. CHARLES M. McKENNA, Chicago: Dr. Folson's remarks concerning sutures is correct. It is seldom that I introduce a suture in the closing of a ureter. I believe it is indicated when one is repairing the ureter after a rupture or injury. This is done after a catheter is introduced. If one

suture is introduced after the distal and proximal ends are brought together, the ureter will heal. The second point concerns the ruptured urethra. I have done away with the open operation in this type of injury. At least I have done most of the operations by doing a suprapubic cystotomy and introducing one sound into the posterior urethra through the bladder, while the other sound is passed through the meatus down through the urethra until the two sounds click. The sound that I speak of is a modification of the George Davis sound. I have modified it so that the beak is longer, in order to make it easier to pass back into the bladder. After the sounds click, they are pushed back into the bladder through the meatus. The distal end of the mushroom catheter is threaded onto the sound already in the bladder, and the sound is withdrawn through the urethra which pulls the distal end of the catheter through the meatus. The indwelling catheter then forms a splint for the urethra. This technic does away with an external urethrotomy. If one feels that the broken ends of the urethra are not in contact, it is simple enough to cut and introduce a suture.

CLINICAL SIGNIFICANCE OF ROENTGENOMETRY IN OBSTETRICS

HERBERT THOMS, M.D.

NEW HAVEN, CONN.

Nearly 400 years has elapsed since Arantius¹ (1572) pointed out the importance of the configuration of the bony pelvis in its relation to the successful outcome of labor. At first glance, therefore, it seems surprising that only within our own time has accurate knowledge become available regarding the shape and size of the bony pelvis in the living subject. It is a fact, however, that until the advent of roentgen methods of pelvimetry such information was lacking. Furthermore, the most significant pelvimetric maneuver up to this time was that first described by Smellie² and later by Baudeloque³ for determining the diameter of the diagonal conjugate.

That roentgen pelvimetry has not been more generally employed is probably due to a number of factors, namely,

1 The majority of women will be delivered spontaneously whether or not pelvic measurements of any sort are made.

2 The medical profession does not readily adopt suggested changes in an established routine method of handling obstetric cases.

3 The adoption of new diagnostic methods often increases the patient's expense.

4 The present methods of estimating the degree of disproportion, such as palpation of the fetal head and the test of labor, although entirely speculative, are apparently satisfactory in many cases.

5 In the majority of instances, roentgen pelvimetry cannot be performed by the obstetrician himself but requires the assistance of a roentgenologist.

6 The great value of roentgenometric diagnosis is generally unappreciated.

Of course other factors may be involved, but it is certain that none of those just named present a sound argument against the use of roentgenometry in obstetrics. The value of this procedure rests on the following thesis.

If knowledge of the shape and size of the bony pelvis is indispensable to the practice of scientific obstetrics, roentgen pelvimetry is a sound procedure and its routine use particularly in primiparous patient, is also indispensable.

With respect to external pelvimetry as applied to the pelvic brim I can only repeat what I have recently pointed out in a comparative study of pelvises, that measurements so obtained are significant only as guideposts and, in certain instances may even be misleading.

In this paper I shall indicate what my own experience with roentgen pelvimetry has taught me. I shall not discuss technical procedures beyond stating that the method which has been developed in this clinic is an unusually desirable one in that it is accurate, simple and inexpensive. Moreover, in the great majority of cases a satisfactory roentgenogram can be obtained by the use of sensitized paper, a type of film that we have recently adopted. Paper film has a great advantage over the celluloid film, since the paper record can be incorporated in the history and filed with other pertinent data.

Early in our work we learned that external pelvimetry fails to give uniformly accurate information as to the shape and size of the superior strait. This is especially true in certain thin, undersized individuals. In many patients of this type, although the external pelvic measurements suggest a generalized pelvic contraction, the roentgenograms disclosed a relatively capacious pelvis and spontaneous birth of the normal size infant was the rule. On the other hand we noted that in many thick boned, short, squatty individuals with similar external measurements the roentgenograms revealed the presence of contracted pelvises, and these patients of course presented during labor the problems usually associated with that entity.

In certain of our cases we found a moderate pelvic contraction, which was limited almost wholly to the transverse diameter of the superior strait. This phenomenon interested us greatly, particularly because we came on an increasing number of pelvises that presented this anomaly. In a relatively large group the length of the transverse diameter was so shortened as to equal that of the anteroposterior diameter. In some instances the transverse diameter was actually less than the anteroposterior diameter, a characteristic of a true dolichopellic or "anthropoid" pelvis.

Because of the apparent relationship between a shortening of the transverse diameter and a primary or transient and a secondary or persistent, occipitoposterior presentation, accurate information regarding the length of this diameter is of clinical importance. My first communication,⁴ in 1930, emphasized this point with respect to generally contracted and simple flat pelvises. In another communication,⁵ in 1932, I reviewed my observations on sixteen consecutive patients in whom the fetus presented either in an occipitoposterior or high transverse position. In every pelvis of this group there was a relative or real shortening of the transverse diameter of the superior strait. In May 1932 I⁶ presented to the American Gynecological Society my observations on twenty consecutive patients whose pelvises showed a relative or real shortening of

the transverse diameter of the superior strait In every instance a primary or secondary occipitoposterior position was found when the patient fell into labor In this paper I stated that the extraordinary incidence of primary and secondary occipitoposterior presentations noted indicate that this type of pelvis is a most potent factor in the production of this position In a previous paper I have suggested the reason for this mechanism and have pointed out that an actual or relative shortening of the transverse diameter of the superior strait results in a limitation of space that is greater in the anterior than in the posterior half of the superior strait Under these circumstances it appears that when the head descends at the beginning of labor the occiput is forced to rotate posteriorly This point of view is substantiated by the recent work of Caldwell and Moloy,⁹ who state that "in the anthropoid type of pelvis engagement is possible only in the anteroposterior diameter, as compensation exists in the posterior pelvis, the anterior part of the inlet being narrow" These authors are to be congratulated for their excellent work on the classification of pelves If the reader will acquaint himself with the terms "gynecoid," "android" and "anthropoid" as used by them he will recognize two facts first, the importance of such a working classification as suggested by Caldwell and Moloy, and, second, the importance of the clinical application of roentgen pelvimetry It has become a dictum in our clinic that, when an "anthropoid" type of pelvis is diagnosed antepartum, a primary and possibly a secondary occipitoposterior presentation may be expected during labor It will be readily appreciated that, when the occiput is directed obliquely posteriorly in an anthropoid pelvis, a modification of the usual method of delivery by forceps may facilitate the mechanism of descent through the pelvic canal A similar modification of method may be applicable in the extraction of the aftercoming head in breech deliveries In both these conditions the aim is to enable the fetal head to pass through the canal to the best mechanical advantage

As our studies in roentgen pelvimetry progressed, we felt the additional need of a method of determining the size of the fetal head in utero In developing this method we noted the frequency with which the unengaged fetal head lay with the occipitofrontal diameter parallel to the transverse diameter of the superior strait, with the occiput directed either to the right or to the left Under these circumstances if the patient is placed in a supine position a roentgenogram of the fetal head in utero will cast a shadow which is really an enlarged profile of the fetal head By adapting this method of roentgen pelvimetry, measurement of the occipitofrontal diameter of the head in utero becomes a simple matter¹⁰ On many occasions we have checked the method of cephalometry by determining the diameter of the unmolded head before and after cesarean section and have found that the procedure yields accurate results Information regarding the length of the occipitofrontal diameter has given us a useful means of computing the biparietal diameter and here again our figures have checked with a surprising accuracy

As these studies progressed it occurred to us that information regarding the length of the occipitofrontal diameter might be helpful as a means of determining the maturity of the fetus in utero¹¹ The analysis of a

large number of fetal weights and measurements, which included the diameters of the head and the body length, showed that the relation of the length of the occipitofrontal diameter to these measurements was quite constant This was especially true with respect to the crown heel measurement We have successfully made use of this information in determining the maturity of the fetus in utero, the importance of which is obvious when the induction of labor is considered in patients suffering from a toxemia, cardiac complications or pulmonary tuberculosis

As experience in interpreting the results of roentgenometric pelvimetry increases, the so-called test of labor should be less employed In making this statement I do not underestimate the importance of the force of the uterine contractions or the ability of the fetal head to mold These also are important factors of the problems associated with disproportion On the other hand, it should be realized that the greater the exact knowledge of all the factors concerned in the problem of disproportion, the less reliance will be placed on the rule of thumb methods now in use

I have a firm conviction that roentgen pelvimetry has a distinct place in the examination of every primiparous woman Many times I have examined patients whose external measurements were within the limits of normal but whose pelves were in reality contracted On the other hand, certain patients whose external measurements have been so shortened as to suggest the advisability of delivery by cesarean section have been shown by roentgenometry to have adequate pelves and have been delivered spontaneously

CONCLUSION

In concluding this short review of my present attitude toward roentgen methods as applied to clinical obstetrics I should perhaps mention their importance in the diagnosis of fetal position, the presence of fetal abnormalities, the presence of multiple pregnancy and perhaps more especially in the diagnosis of a rachitic deformity of the sacrum¹² Certainly, as was pointed out in the first part of this paper, recent knowledge of the wide incidence of the android and the anthropoid type of pelvis in otherwise "normal" individuals makes a knowledge of these conditions imperative for the practice of scientific obstetrics Finally, I would recall our recent adoption of a technic in which sensitized paper is being used instead of a celluloid film This technic, together with the ability of making pelvigrams of several patients at one appointment, has reduced the cost of the procedure to a real working basis for ward patients

Pneumothorax Treatment for Bronchiectasis—I feel pretty certain that if bronchiectasis were always diagnosed early—as it indeed should be nowadays since the use of iodized oil has proved an infallible method of demonstrating the presence of dilated bronchi—and if the pneumothorax treatment were always initiated as soon as the diagnosis had been established the proportion of recoveries would increase very substantially Many years were lost before the necessity of early pneumothorax treatment in ulcerative tuberculosis of the lung was universally admitted But since it has been admitted, the proportion of successes has become considerably greater than it was in the days when pneumothorax was regarded as an exceptional measure and, so to say, as a last resource I venture to predict that the pneumothorax treatment of bronchiectasis will be a repetition of the same story—Rist E Collapse Therapy of Bronchiectasis, *Ann Int Med* 7 417 (Oct) 1933

Clinical Notes, Suggestions and New Instruments

CORTIN IN THE TREATMENT OF PROGRESSIVE MUSCULAR DYSTROPHY

RALPH W. MENDELSON, M.D., ALBUQUERQUE, N. M.

In reporting this case I am not unmindful of the fact that conclusions may not be drawn from a single observation, yet results were so prompt and even spectacular that I am prompted to call attention to the treatment used in order that others working in a larger field may try it out and, if found successful, render at least symptomatic relief to a class of patients at present more or less incapacitated.

After twenty injections of cortin patient able to rise from floor without assistance

A man aged 30, a Mexican, first noticed some weakness in his left arm and hand about July, 1930. At that time his weight was 131 pounds (59.4 Kg.) and he was working as a stock clerk in a general store. This weakness and loss of power gradually increased with no periods of intermission up to the time he applied for treatment, July 6, 1933. On that date he tried to shift a keg of nails and found to his surprise that he was unable to do it.

The family history was negative, there were no other cases and there was no history of tuberculosis, cancer, or nervous or mental diseases. The patient's past history was irrelevant, he had had mumps, measles and typhoid. There had been no surgical operations and his habits were normal. He stated that he had had no venereal diseases. The patient complained of loss in weight, transient pains in the affected muscle groups, extreme weakness, inability to walk, insomnia and loss of sexual power.

The patient was emaciated, weighing 103 pounds (46.7 Kg.). He had some difficulty in swallowing, a slight disturbance in his speech and marked atrophy in the following muscles: the pectorals, latissimus, serratus magnus, rhomboids, trapezius, biceps, brachials, supinator longus and triceps, erector spinae, the glutei and the thigh muscles. There were no fibrillary contractions, the reflexes were practically normal and sensation was unimpaired. The sphincters were not affected.

The Wassermann reaction was negative, the red blood cell count was 5,500,000 and hemoglobin 90 per cent on the Dare scale. The urine and stool examinations were negative. The white count was normal and the blood pressure was 90 systolic, 70 diastolic.

The treatment suggested itself in view of the fact that, although the patient suffered from a distinct disease entity he presented himself as having "progressive asthenia," and although I entertained no hope for a cure I felt that if cortin relieved his symptoms to a degree it would be worth while.

I started treatment, July 30, using 1 cc of cortin subcutaneously every day for ten days. There was no particular change

at the end of that time. In view of the cost of the cortin I was forced to limit the injections to once every three days. At the end of the second ten injections the patient stated that his cramplike pains had left, he was able to sleep and his appetite had materially increased. His sexual power was returning and he could walk without assistance. At the present time, Oct. 25, 1933, his weight is 108½ pounds (49.2 Kg.). The blood pressure is 110 systolic, 80 diastolic, he can ride a bicycle several blocks and a few days ago went dove hunting, walking a distance of about 5 miles and carrying a shotgun. His speech difficulty and swallowing have returned to normal. He is an entirely different man and his outlook on life that of a normal human being.

If cortin should act only 50 per cent as well in this type of disability as insulin does in diabetes it would be well worth while. It is hoped that others will try it out and report on a series of cases.

FOREIGN BODIES IN STOMACH

E. RAYMOND HILDRETH, M.D., BAY SHORE, N. Y., AND
ROBERT B. CASEY, M.D., CENTRAL ISLIP, N. Y.

This case is reported because of its general interest and to add it to the literature on the curiosities of medicine.

M. H. L., a woman, aged 46, married, was admitted to the State Hospital at Central Islip, Feb. 10, 1932. The diagnosis was involution melancholia with suicidal tendencies.

Sept. 6, 1933, she vomited and complained of constipation. A large hard mass was palpable in the upper left quadrant of the abdomen. Liquid petrolatum and enemata were administered daily, with little appreciable effect on the mass. September 11, a roentgenogram showed a mass of what appeared to be metallic spoons in the stomach. September 12, a laparotomy was performed. An incision was made in the upper anterior surface of the stomach and the following objects were removed: forty-eight teaspoons, one tea spoon handle, three bolts, one nut, one prune pit, one button,

Fig. 1—Appearance of stomach September 11 suggesting metallic mass.

Fig. 2—Articles removed from stomach, September 12

one small piece of glass, two pieces of spring wire, one needle, one piece of cinder, one hair pin and one lead pencil.

Recovery from the operation was uneventful except for slight infection of subcutaneous tissue. The mental condition continued disturbed, requiring restraint.

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH Secretary

DIPHTHERIA TOXOID, ALUM PRECIPITATED (REFINED)—Diphtheria Toxoid (Havens)—The work of Havens and others has shown that diphtheria toxin modified by the method of Ramon may be precipitated by the addition of potassium aluminum sulphate. The resultant water insoluble precipitate, which contains the antigenic properties, is purified by washing. More than 50 per cent of the proteins contained in the original crude toxoid are removed during the process of purification.

Actions, Uses and Dosage—Refined diphtheria toxoid, alum precipitated, is used for active immunization against diphtheria. It is administered subcutaneously, preferably at the insertion of the deltoid muscle, in one dose. Owing to the presence of potassium aluminum sulphate in the product, absorption is delayed. A nodule persists at the site of inoculation for several days.

The National Drug Co., Philadelphia

Refined Diphtheria Toxoid (Alum Precipitated)—Prepared from a seven day culture of the diphtheria bacillus which yields toxin having an L₁ dose of not more than 0.2 cc. The toxin is treated with formaldehyde until its toxicity is so reduced that five human doses will cause no local or general symptoms of diphtheria poisoning when injected subcutaneously, into guinea pigs. The toxoid is precipitated with a solution of alum washed and then suspended in physiologic solution of sodium chloride to which merthiolate has been added. The product is tested for antigenic potency according to the method prescribed by the National Institute of Health guinea pigs weighing 500 Gm. given one human dose must produce at the end of six weeks at least two units of diphtheria antitoxin in each cubic centimeter of blood.

Marketed in packages of one 0.5 cc vial, one 5 cc vial and ten 0.5 cc vials representing respectively one, ten and ten immunizing doses.

E. R. Squibb & Sons, New York

Refined Diphtheria Toxoid Alum Precipitated Squibb—Prepared by treating diphtheria toxin with a solution of alum until complete precipitation is produced. The precipitate is washed with and suspended in physiologic solution of sodium chloride. The product is tested for antigenic activity according to the method prescribed by the National Institute of Health guinea pigs weighing 500 Gm. given one human dose must produce at the end of six weeks at least two units of diphtheria antitoxin in each cubic centimeter of blood.

Marketed in packages of one 0.5 cc vial and in packages of one 5 cc vial representing one and ten immunizing doses respectively.

PARKE-DAVIS HALIVER OIL, PLAIN (See THE JOURNAL Nov 18 1933, p 1634)

The following dosage form has been accepted:

Soluble Gelatine Capsules Parke Davis Haliver Oil Plain 3 minims
Each capsule contains Parke-Davis haliver oil plain 3 minims with sufficient cod liver oil to fill the capsule.

REPORTS OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT
PAUL NICHOLAS LEECH Secretary

OCTOZONE NOT ACCEPTABLE FOR N N R

The Octozone Corporation of America presented for the consideration of the Council a labile gaseous preparation called Octozone and the apparatus ('Electroniseur') for preparing this gas from oxygen by the action of an electrical discharge. The product is proposed for the treatment of a large variety of diseases in particular various forms of arthritis by local application by baths in closed bags by subcutaneous or intramuscular injection, by rectal administration or by mouth dissolved in water.

In the letters from the firm and in the submitted literature it is admitted that Octozone is a misnomer for the polymer of oxygen known by this name that the evidence indicates that the gas is not O₃ as suggested by the inventor of the apparatus Eugene Rover of Lyons France. The French War Office is stated to be of the opinion that the gas may better be design-

nated as O₄. The evidence submitted by the firm to show that the gas is not ozone was based on effects that appear to differ from those of the usually available concentrations of ozone only quantitatively, the latter gas in sufficient concentration will cause both marked and rapid deterioration of rubber and 'solidification' of mercury, these phenomena were claimed by the firm to be characteristic of "Octozone" and not of ozone. As to relative effects on subcutaneous injection of ozone and "Octozone," the Council's referee has no data other than the statement of the firm that "oxygen (O₂) or ozone (O₃) injected subcutaneously or intramuscularly in the human, or experimentally in the animal, leaves a bleb or swelling lasting for a considerable time. OCTOZONE injected subcutaneously or intramuscularly even in large quantities (250 or 300 cc) develops a very transitory swelling which rapidly disappears, in contrast to the above, giving but momentary sense of burning."

On request from the secretary that more adequate data be furnished with regard to composition of the gas, the firm enlisted the assistance of Prof. Arthur W. Ewell of the Worcester Polytechnic Institute, a recognized authority on ozone. Professor Ewell, as a result of his study, concluded that the higher form of oxygen produced by the "Electroniseur" is ozone. Professor Ewell's conclusion "is in agreement with all published experimental evidence, since this gives no evidence of the presence of anything but ozone at concentrations comparable with those given by this apparatus."

As the evidence seems to be fairly conclusive that "Octozone" is a mixture of O₂ and O₃, the Council decided that no proprietary name for the gas could be recognized, since ozone is not a new discovery, either from a chemical or from a therapeutic standpoint.

The Council found the evidence of therapeutic usefulness submitted by the firm unconvincing. It appears that, under the impression that the gas was a new preparation, investigators have used it on patients without preliminary work on animals. At least such work was not reported in the available data. However, the firm stated "We have carefully followed the experiences of those who are using the apparatus here, and also have instituted a series of bacteriological and animal experiments to confirm the observations of investigators in England and France." The results of the latter investigations have not been submitted to the Council.

The case reports, all of which are from France and England, are without exception uncontrolled and the information provided is far from complete. In some of the reports the alleged results defy credibility, for instance, 20 cc Octozone injected deep into forearm muscles is claimed to have resulted in recovery without recurrence in an old case of malignant tertian malaria. Or, again, two 400 cc injections of Octozone by rectum are said to have cleared up symptoms of internal hemorrhoids.

In the treatment of arthritis the patients are usually enclosed in gas tight bags tightly fitted about the neck which are then filled with Octozone for variable periods, according to the reports. The "baths" are repeated at intervals. In the treatment of cutaneous ulcers, the gas is sprayed directly on the lesions. It is also suggested that colds may be aborted by intranasal application. Among the various conditions treated with Octozone are furunculosis, varicose ulcer, fibrositis, ulcerative colitis, sciatica, 'rheumatism,' subphrenic abscess, osteomyelitis, cystitis, hemorrhoids and Oxyuris vermicularis infestation.

It is difficult to understand how ozone (which in concentrations of 5 to 10 parts per million cannot be inhaled without severe irritative effects leading even to fatal pulmonary edema) can be injected into the colon or under the skin in much higher concentration without dangerous effects. About fifteen years ago investigations made for the Council in testing ozone devices proposed for purifying the air showed that germicidal concentrations were very highly irritant to the respiratory passages. The use of ozone in the treatment of wounds, for instance is not new and according to G. Stoker, who employed it fairly extensively before and during the war, it has a field of therapeutic usefulness although this is very limited. This is upheld also by Solis-Cohen and Githens (Pharmacotherapeutics, New York 1928 D. Appleton & Co. p. 495) who report similar

results It appears, then, that the intelligent employment of ozone may yet find for it a therapeutic niche But such use as it has so far received under the name "Octozone," judging from the available data, cannot but further discredit the employment of this oxidizing agent in the treatment of disease No controlled experiments made with oxygen or air alone were reported, apparently no effort was made to determine whether or not the marked perspiration incident on the 'baths' may have been a factor in the reported improvement of some of the cases little or no objective data indicating recovery is furnished the gas apparently has been administered by every imaginable route, with seemingly reckless abandon

A statement of the Council's consideration of Octozone was sent to the manufacturer with the usual request that the firm consider means of making the product acceptable No reply having been received from the firm after the lapse of three months, another letter was sent by registered mail The firm again failed to reply The Council declared Octozone unacceptable for New and Nonofficial Remedies because, according to the available evidence, it is the well known ozone marketed under a proprietary name with extravagant, unwarranted and even dangerous therapeutic claims

HERSHEY'S MILK CHOCOLATE

HERSHEY'S MILK CHOCOLATE (5 cents)

HERSHEY'S MILK CHOCOLATE PENNY BAR

HERSHEY'S MILK CHOCOLATE KISSES

Distributor—Chocolate Sales Corporation, Hershey, Pa

Manufacturer—Hershey Chocolate Corporation, Hershey, Pa
Description—Milk chocolate, containing cane sugar, milk, cacao butter and chocolate

Manufacture—Milk produced under company inspection and regulation, conforming to standards of New York and Pennsylvania, is pumped to holding tanks, where a definite quantity of sucrose is added The sugar-milk solution is condensed under "vacuum" to a viscous mass, machine mixed with the formula proportions of "chocolate liquor," dried to a coarse powder, thoroughly ground with a specified quantity of cacao butter is standardized to a proper viscosity with more cacao butter if necessary, molded into desired shapes, and automatically wrapped in aluminum foil

VAN CAMP'S PURLED PRUNES

Manufacturer—Van Camp's, Inc., Indianapolis

Description—Sieved prunes largely retaining the vitamins and all the mineral content of the prunes used

Manufacture—High grade medium sized prunes are carefully inspected to eliminate any unsuitable material, are washed in a cylinder equipped with high pressure cold water sprays and are covered with a minimum amount of water, and the temperature is slowly raised to simmering and held there till the prunes are swelled and softened The prunes and juice are drawn off and passed through a pulping machine to remove the pits the mass is sieved through a screen with openings of a size to produce the desired fineness and texture, is adjusted with hot water to the desired consistency, and is heated and filled into caramel lined cans, which are sealed and processed

DAVIDSON'S SPUN BREAD SLICED (WHITE)

Manufacturer—Davidson Baking Company, Portland, Ore.

Description—A white bread made by the sponge dough method (method described in THE JOURNAL, March 5, 1932, p 817), prepared from patent flour, water, powdered skim milk, sucrose shortening salt, yeast, a yeast food containing calcium sulphate, ammonium chloride, sodium chloride and potassium bromate, malt syrup, and a yeast food containing buttermilk, calcium phosphate and ammonium tartrate The dough is twisted, which accounts for the name "Spun"

RADIOLOGIC SERVICE IN THE UNITED STATES

REPORT BY THE COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

The fourth publication of the Council's list of physicians specializing in radiology contains the names of 1,250 physicians. These have been found to comply with the "Essentials" that were formulated by radiologists and ratified by the House of Delegates of the American Medical Association.

The Council's first survey covered mainly those radiologists who were conducting laboratories of their own and included those that were connected with hospitals but did not include others, such as those who teach and supervise radiologic work in medical schools and those working in research institutions and government departments. More recently, the work has been extended to all of these fields. To assist the Council in preparing this first survey, the officials of the two leading radiologic societies cooperated with the Council's special committee by appointing qualified radiologists in all parts of the country to act as advisers. These advisers examined the credentials of applicants from their respective localities, made inspections, and advised which candidates could qualify, according to the "Essentials." This original list contained the names of 930 physicians.

From the beginning of this work the Council has emphasized the fact that the practice of radiology is the practice of medicine. The field of radiology had attracted ambitious persons of a mechanical turn of mind for the reason that the work employs mechanical devices and it appears to the uninformed public that little training or special knowledge is necessary. A large number of lay persons trained as technicians had

established radiologic laboratories. In many instances, physicians themselves patronized these laboratories and thus fostered them. Often lay controlled and operated laboratories hire physicians to sign their reports and otherwise "use" their names. The designation by the Council of those qualified in radiology has been far reaching in its effects. The principles of medical ethics have been effectively stressed. Without doubt, numerous practicing physicians have been weaned away from supporting lay specialists in this field. The opposition to lay practitioners entering x-ray work independently has been efficacious. Improperly qualified physicians are being dissuaded from holding themselves out as radiologists. Instances are not lacking in which certain practicing radiologists have been induced to improve their business methods and in some instances to withdraw the use of their names from lay "picture factories." By the regular publication of lists of accredited radiologists, physicians generally are encouraged to refer their work to qualified medical graduates.

The excellent cooperation given the Council by the national radiologic societies and the advisers in the various sections who are themselves prominent radiologists, has made possible the development of the Council's present list. The maximum value and the continued wholesome effects of this published list are in direct proportion to the cooperation extended by the physicians in the specialty.

Doubtless there are radiologists who have not made application for the Council's listing and whose names have not been included for that reason.

ESSENTIALS FOR ADMISSION TO LIST OF PHYSICIANS SPECIALIZING IN RADIOLOGY

Prepared by the Council on Medical Education and Hospitals

PHYSICIANS ELIGIBLE

Consideration for admission to the list is open to all regular licensed physicians engaged in radiologic work in accordance with the essentials whether connected with a hospital or conducting an independent laboratory.

1. QUALIFICATIONS

(a) The candidate shall be a graduate of a medical school that is approved by the Council on Medical Education and Hospitals and shall be licensed to practice medicine in the state in which his department is located. He shall also have had special training, such as is approved by the Council in radiology, roentgenology or radium therapy at an acceptable school—preceptorship hospital or clinic, department of radiology, roentgenology or radium therapy—for a period of at least three years. He must be a man of good standing in the medical profession and particularly among those specializing in radiology. He shall either be on a full time basis or have definite hours of attendance at the department, such hours to be ample to insure the element of medical consultation in every examination or treatment.

(b) The department shall be under the direction of a physician radiologist, roentgenologist or radium therapist as the circumstances may require. The director shall be responsible for all examinations and treatments. He shall be responsible

for all professional assistants and for the efficient maintenance of the department.

Physicians employed by laboratories which are under lay control and direction will not be eligible for consideration for this listing.

(c) *Assistants*—The director may have a corps of qualified medical and technical assistants responsible to him and for whom he is responsible, to carry out accurately the various functions of the department.

2. DEFINITIONS

Radiology—The branch of medicine which deals with the diagnostic and therapeutic application of radiant energy, including roentgen rays, radium, ultraviolet rays and other spectral radiation.

Department of Radiology—A private laboratory or department of a hospital, clinic or other institution organized and equipped for the diagnostic and therapeutic application of radiant energy, in the form of roentgen rays and radium. Ultraviolet and other spectral radiation may also be included.

Radiologist—A qualified physician who also has obtained adequate training and experience in general radiology. Physical therapy is not obligatory under this classification.

Roentgenology—The phase of radiology which deals with the diagnostic and therapeutic application of roentgen rays only.

Department of Roentgenology—A private laboratory or department of a hospital, clinic or other institution organized and equipped for the diagnostic and therapeutic application of roentgen rays only. A department organized and equipped solely for the diagnostic or therapeutic application of roentgen rays shall be known as a department of diagnostic or therapeutic roentgenology, respectively.

Roentgenologist—A qualified physician who has had adequate training and experience in the diagnostic and therapeutic application of roentgen rays.

Diagnostic Roentgenologist—A roentgenologist who limits his practice to the diagnostic phase of roentgenology.

Therapeutic Roentgenologist—A roentgenologist who limits his practice to the therapeutic phase of roentgenology.

Radium Specialist—A physician who has had adequate training and experience in the therapeutic use of radium and who specializes in this work.

3 SCORE

A department of radiology should be able to render all of the following services:

(a) Roentgenography, simple or stereoscopic of any part of the body, with medical interpretation of the roentgenographic observations, and under satisfactory conditions for the protection of the patient and of the professional and technical personnel.

(b) Roentgenoscopy of any part of the body in any position, with or without opaque mediums, with medical interpretation of the roentgenoscopic observations and under satisfactory conditions for the protection of the patient and the professional and technical personnel.

(c) Roentgenotherapy of all benign and malignant diseases amenable to such treatment with roentgen rays generated at low, moderate or high voltage (long, medium or short wavelength), as the conditions may require, and under satisfactory conditions for the protection of the patient and of the professional and technical personnel.

(d) Radium therapy of all benign and malignant diseases amenable to such treatment with an adequate quantity of radium element or emanation and under satisfactory conditions for the protection of the patient and of the professional and technical personnel.

Ultraviolet therapy, general or local, with satisfactory air-cooled and water-cooled quartz mercury lamps or carbon arc lamps, with suitable quartz and other applicators for irradiation of cavities, sinuses or the superficial lesions under pressure, and under satisfactory conditions for the protection of the patient and of the professional or technical personnel. The Council recommends that, wherever ultraviolet treatments are given, they should be under the control and supervision of a physician who has specialized in this form of radiant energy.

A department of roentgenology should be able to render the services specified under *a*, *b* and *c*.

A department of diagnostic roentgenology should be able to render the services specified under *a* and *b*.

A department of therapeutic roentgenology should be able to render the services specified under *c*.

A department of radium therapy should be able to render the services specified in *d*.

4 HOUSING

The housing should be adequate for the proper functioning of the department of radiology or roentgenology. Damp or ill ventilated quarters are unsuitable for such work.

5 EQUIPMENT

The equipment should be sufficient to carry out properly the technical procedures and activities of the department of radiology, roentgenology or radium therapy.

6 PROTECTION

The arrangement of working rooms and conditions, and the construction of all apparatus shall be such as to provide adequate protection, both from electrical shock and from avoidable exposure to roentgen rays or radium to patients, attendants and other persons in or near the department. The requirements in this respect are based on the recommendations adopted

by the International Congress of Radiology, held at Stockholm, Sweden in July 1928 and approved by the American Roentgen Ray Society and the Radiological Society of North America.

7 RECORDS

Full records of all examinations and treatments made by the department, suitably indexed, are essential. Roentgenograms made in the department should have inerasable identification marks which will preclude error as to patients concerned. Roentgenograms may be lent to referring physicians but should be returned to the laboratory for filing and future reference. Suitable storage facilities should be provided where roentgenograms and other records will be both safe and readily available for reference. They shall be kept as long as there is the possibility of their being needed for the benefit of the patient or their physicians.

As roentgenography constitutes only a kind of medical examination on which the roentgenologist's opinion of the patient's condition is partly or wholly based, and as the opinion of the specialist is the essential factor, the Council holds that the introduction of roentgenograms as evidence in medicolegal cases should be discouraged as immaterial and as tending to adulterate the process of justice. There is no more reason for the introduction of roentgenograms than for requiring a pathologist to bring to court his microscope and his sections of tissues.

8 REPORTS

The reports of a department of radiology, roentgenology or radium therapy shall be made through the director on stationery or blanks having the name of the director printed thereon. Under no circumstances shall roentgenologic diagnoses, interpretations, opinions, statements of prognosis or therapeutic suggestions be offered by the nonmedical personnel.

9 LIBRARY

The department of radiology, roentgenology or radium therapy should be provided with or have convenient access to a library including current scientific books and journals on all the various subjects required in its work.

10 ETHICS, FEES AND PUBLICITY

Radiology is a special type of medical practice and the physician practicing radiology is subject to the same rules of special training and conduct that govern his fellow specialists in the practice of medicine and surgery. The Principles of Medical Ethics of the American Medical Association shall apply in all cases. The fees charged for radiologic services shall be under the control of the director of the department. All systems of rebates, discounts, special group rates, etc., shall be considered unethical except that where the patient's economic status is the determining factor, the radiologist, like his fellow physician in medicine or surgery, may waive part or all of the fee.

The publicity of a department of radiology, roentgenology or radium therapy should be in professional good taste and limited to statements of fact as to name, address and telephone number, names and titles of the director and other active responsible personnel, field of work covered, office hours, directions for referring patients, and so forth. It should not contain misleading statements or claims of unusual superiority. It should not advocate medical fads nor lay undue stress on the importance of roentgenologic observations. On the letter heads or any other form of publicity only the names of those rendering regular services to the department should appear as being connected with the department. Advertising matter should be directed only to physicians, either through bulletins or through recognized technical journals, and never to the nonprofessional public, as, for example, by announcements in popular journals and periodicals, circulars, pamphlets or telephone lists.

11 ADMISSION TO THE APPROVED LIST

Only when the physician is the director or is affiliated with a department of radiology, roentgenology or radium therapy in which the personnel, space, equipment, management, finances and records are such as will insure honest, efficient and accurate work may he expect to be listed. Physicians desiring to be considered for the approved list should apply to the Council on Medical Education and Hospitals of the American Medical Association, 535 North Dearborn Street, Chicago.

PHYSICIANS SPECIALIZING IN RADIOLOGY—1,250

The list contains the names of only those who have applied for recognition and who have been found to comply with the "Essentials." The advisers for their respective states have passed favorably upon them. Those who are still under consideration, and others who may apply, will when accepted, be added in subsequent issues of THE JOURNAL.

The type of service rendered is given opposite the name "Radiology," under "Type of Service" always includes short wave therapy, also known as "deep therapy." The asterisk (*) on "roentgenology" indicates that short wave therapy is included.

For list of physicians specializing in radiology in government service, see page 618

RADIOSENSITIVITY OF TUMORS

The relative differences of tumors in sensitivity to roentgen and radium rays are worthy of special study by the clinician, pathologist and radiotherapist. Much information has already been accumulated concerning the reaction of various cells and tissues to radiation. Embryonal tumors, as well as tumors composed of rapidly growing cells, are sensitive to radiotherapy. Lymphoid cells are particularly susceptible to radiation. On the contrary, neurosarcoma, glioma and melanoma are radioresistant.

Stewart¹ defines radiosensitivity as that combination of circumstances resident in the tumor or the host which permits marked or total local tumor regression under doses of radiation sufficiently small to preserve the integrity of the tissues of the host. Degrees of radiosensitivity are recognized. Ewing² classified tumors in decreasing order of radiosensitivity as follows: (1) lymphoma, (2) embryonal tumors, (3) cellular anaplastic tumors, (4) basal cell carcinoma, (5) adenoma and adenocarcinoma, (6) desmoplastic tumors, such as squamous carcinoma and fibrocarcinoma, and (7) fibroblastic sarcoma, osteosarcoma and neurosarcoma. Local conditions that may influence the response to radiation are the histologic type, vascularity, fibrosis, amount of fat tissue, presence of infection, metastases, and previous operations.

The histogenic study of a tumor affords an important criterion by which to judge radiosensitivity. As Borak³ indicates, the radiosensitivity of a tumor is no accidental attribute but rather the expression of cell structures as well as the biologic qualities of the parent tissue. There are other factors that complicate the problem. The location of a tumor in bone or fat tissue renders it radioresistant. Active infection interferes with successful irradiation. Highly vascular tumors vanish rapidly under irradiation, as a result of necrosis of the capillary endothelium. An important fact

emphasized by Ewing is the increased resistance to radiation acquired by a tumor after successive treatments with inadequate dosage. Likewise tumors may become radium fast after a series of treatments with high dosage. Paradoxical differences are observed in tumors when the degree of malignancy is compared with their radiosensitivity. The estimation of these differences is an urgent and difficult task for the pathologist and the radiotherapist. Thus, Ewing presents a list of comparative reactions in epidermoid carcinoma: 1. Squamous cell carcinoma of various grades of malignancy is radiosensitive. 2. Transitional cell carcinoma is highly malignant and radiosensitive. 3. Schneiderian carcinoma is highly malignant and radiosensitive. 4. Basal cell carcinoma is of comparatively low malignancy and radiosensitive. 5. Lympho-epithelioma is highly malignant and very radiosensitive. Markedly anaplastic tissues show increased malignancy and radiosensitivity. Many of these differences in response to radiation become clearer if it is remembered that radium rays arouse similar variations in the reaction of normal cells. Vascular endothelium, lymphatic tissues, leukocytes and ovarian follicles are rapidly destroyed, whereas nervous, fibrous and cartilaginous cells are much more resistant.

The clinical irradiation of tumors is based on this selective action of the rays. Desjardins⁴ asserts that the specific sensitiveness of each kind of cell is the dominant single fact of radiology and deserves to be recognized as a law. This sensitiveness seems to be related to the natural life cycle. The lymphocytes, whose metabolic life cycle is shortest, are the most sensitive, while the nerve cells, whose life cycle is longest, are also the most resistant to radiation. Desjardins states that the susceptibility of tumors to irradiation agrees closely with the radiosensitiveness of normal cells of the same kind from which the tumors are derived. However, morphology is not completely adequate for the estimation of radiosensitivity. The general condition of the patient and his constitution also modify the effects of radiation. Anemic cachectic individuals respond poorly to radiotherapy. There are probably hereditary, constitutional and nutritional influences that alter the response to irradiation in different patients afflicted with the same morphologic type of tumor. For example, the red-blond type of person who forms inadequate pigment against sunlight also reacts poorly to radiotherapy.

Another important factor in determining and recording radiosensitivity of tumors is the question of dosage. With improvements in apparatus and technic there are discrepancies and differences in the reporting of dosage. The recent establishment of an international unit of quantity, the international r unit, should create more uniformity in this complicated field and rescue it from the state of "haphazard empiricism" so justly depre-

cated by Ewing Roentgen dosage, according to Reinhard,⁵ should be definitely prescribed and reported in terms of wavelength, quantity in roentgens, time, target-skin distance and field size. For each type of tumor there is an optimal radiation dosage. Many discrepancies in the reports seem to be due to uncertainties and differences in radiation dosage.

The artificial increase of radiosensitivity in tumors is a promising field of investigation. Voltz reports on the introduction of metal salts (cerium-iodine) into tumors and the benefits resulting from secondary rays given off by these chemicals after irradiation. Various substances have been used for this purpose by numerous investigators, but the work is still in the experimental stage. Biologic sensibilization is also practiced; pituitary gland irradiation exerts a beneficial effect in malignant conditions of the female genital tract. The radiosensitivity of tumors is a complex problem demanding the cooperation of workers in various fields. As more facts are accumulated, knowledge in this field will become more quantitative and precise. The solution of the problems of radiosensitivity will increase the effectiveness of radiotherapy and extend its rational indications in the treatment of tumors.

ACID-BASE BALANCE AND CARBOHYDRATE TOLERANCE

One of the lessons that physiology and clinical medicine have learned from the development of modern biochemical research involves the continual striving of the living organism to attain certain states of equilibrium. Cannon of Harvard has referred to this as the principle of homeostasis. Metabolism involves an interplay of unlike reactions that tends, in health, to maintain a steady state conducive to the welfare of the body; in disease there may be disruption of this chemical scheme with consequent detriment to well being. As McLester¹ has expressed the situation, for the maintenance of life and the proper performance of function the cells must be surrounded by a medium that at all times maintains an unchanging reaction and fixed molecular concentration. He points out that the mildly alkaline reaction of the blood indicated by the foregoing figure must be maintained at all costs. Yet many products of metabolism are acid in reaction and tend to operate in the opposite direction, while certain abnormal metabolic processes make matters still worse by producing acids in large amounts, such for instance as the formation in diabetes of beta-oxybutyric and other acids. Carbonic acid, and the acids of sulphur and phosphorus which result from protein metabolism, as well as other acids, must be neutralized. This is done chiefly by sodium and potassium and to a less extent by the other basic elements. Ammonia under

certain pathologic conditions is produced in increased amounts and plays a small part in the neutralization of acids, as do also the serum proteins to a slight extent. These last two factors, however, can never bulk large in neutrality regulation, for ammonia is probably toxic and cannot be retained in large amounts, and protein when broken down loses its acid-fixing properties. For purpose of neutralization, the basic elements received from the food are of overwhelming importance.

An apt illustration of what the disturbance of the systemic acid-base balance may involve has been afforded by recent studies of Thompson, Mitchell and Kolb² at Trinity College, Dublin. By administration of liberal quantities of ammonium chloride they succeeded in reducing the alkali reserve of the blood plasma to a level comparable with that found in diabetic coma and to raise the urinary excretion of acid by from 100 to 200 per cent and of ammonia by 30 per cent. The acidosis so produced caused a definite failure in dextrose tolerance shown by hyperglycemia and slow return of the blood sugar to the fasting level following dextrose ingestion, but without any trace of glycosuria.

The association of severe acidosis with diabetes is well known. Joslin³ states that the danger of acidosis varies according to the rapidity of onset, the age of the patient and the condition of the kidneys. It is his impression that fatal coma may result from an acidosis of only moderate degree which has come on suddenly, whereas in another individual the gradual development of an acidosis of equal severity has been borne with comparative ease. The Dublin biochemists regard it as possible that the acidosis of diabetes, which is undoubtedly the severest acidosis encountered in human beings except for some patients moribund from uremia, may have a contributory effect on the changes in carbohydrate metabolism occurring in this disease.

DIGESTIVE LEUKOCYTOSIS

The question as to what variations in the white blood cell count may be regarded as within "normal" or physiologic limitations keeps recurring at frequent intervals. Evidently there is no complete accord as to the answer among students of hematology. The growing evidences have been reviewed in these columns from time to time⁴ in an effort to determine to what extent technical errors, the nature of the diet, mealtime, and muscular or mental activity may induce definite changes. Until these are known it will be difficult if not actually impossible to ascertain what degrees of aberration from the expected leukocyte counts may be ascribed to

pathologic conditions and thus become diagnostic indexes

Garrey and his co-workers at Vanderbilt-University in Nashville have contended that a count above 7,000 per cubic millimeter is evidence of mental or physical unrest and that all "basal counts" lie between the limits of 5,000 and 7,000, whereas investigators at New York University conclude that mild activity has no constant effect on the count, although, as is well known, severe exercise may cause the number of leukocytes to rise to three or four times the normal figure. Garrey and Butler² allege that the low basal leukocyte count of the resting state is unaffected by the intake of large quantities of either protein or carbohydrate. This is one of the last contributions in a sequence of studies that have developed skepticism as to the occurrence of what was formerly designated as "digestive leukocytosis".³

The latest observations on the postprandial distribution of leukocytes as exhibited in white cell counts have been made by Lawrence, Stephens and Jones⁴ at the University of Rochester, N. Y. They studied the effect of ingestion of a large breakfast in normal adult persons. An increase in the total number of white blood cells in the peripheral blood of normal adult subjects has been shown to occur in the majority of instances following the ingestion of food. The increase is not universal in these observations. It is of interest that there is an interval of from one and one-fourth to two and three-fourths hours between the ingestion of food and the initial increase in the total number of leukocytes. This increase is not transient but may be detected up to four hours after the intake of food. The differences between the highest and lowest figures in each of the fifteen individuals for the entire period ranged from 1,600 to 5,750 per cubic millimeter, with an average of 3,249. Corresponding figures for nine basal recumbent subjects were between 1,249 and 3,300. From a clinical point of view, the Rochester investigators conclude, the effect of food on the white blood cell count is not of a great deal of importance, since the increase was not great and in every instance except one the total number of the cells was less than the ordinarily accepted upper limit of 10,000 per cubic millimeter. In round figures, food would never be expected to increase the total count above 2,000 to 3,000 per cubic millimeter. From a purely theoretical point of view, they add, since basal white blood cell counts will show less variation than others, it would seem that these would be most reliable. However, it appears to them that the inconveniences necessitated by the introduction of such procedures in a clinic far outweigh the advantages to be gained.

Current Comment

SELECTIVE REGENERATION AND TISSUE IMMUNITY

The doctrine of "natural variation" in biologic species, with the subsequent "weeding out" of the relatively "unfit," has been a generally accepted law of organic evolution since the middle of the nineteenth century. That similar variations and selectivities are operative with those histologic units which potentially multiply during adult life is suggested by MacNider¹ of the department of pharmacology at the University of North Carolina School of Medicine. His theory of selective histologic evolution, or "regeneration of the fittest," was drawn from studies of kidney repair following experimental toxic nephritis. He found that, after mild toxic injury, renal repair is apparently of the nonselective or nonimmunizing type, the regenerated kidney showing no demonstrable immunity to reintoxication with the same chemical agent. After severer toxic injury, however, renal regeneration is apparently of the evolutionary or selective type, the repaired kidneys having a well marked resistance to such reintoxication. While MacNider makes no assumption that his law of selective regeneration is applicable to the reticulo-endothelial cells, his theory has been received as a valuable working hypothesis in immunology.

SPECIALIZATION IN RADIOLOGY

The rise of roentgenology as a specialty in medicine has been spectacular. The tendency at first to consider it merely a mechanical accessory to diagnosis has been transformed by a realization of the many aspects of its use in the practice of medicine. The literature of the subject is today as advanced and as erudite as that of any other field of medical practice. Nevertheless, the early tendency just mentioned was associated with the commercialization of roentgenology. Indeed, the nature of the work to some extent encouraged such exploitation. One witnesses, for example, the manner in which flat-rate and cut-rate clinics in the field of medical practice, peddling their services by newspaper advertising, offer cheaply the services of a full time roentgenologist as a special bait to the unwary. Among the most important factors in combating this type of effort has been the regular publication by the Council on Medical Education and Hospitals of its standards of competent roentgenologic service and its listing of recognized institutions. Such a list appears in this issue of *THE JOURNAL*, and physicians will do well to familiarize themselves with this phase of the Council's work. There appears also in this issue the announcement of the formation of the new certifying board in roentgenology, organized along the same lines as the boards already established in ophthalmology, otolaryngology, obstetrics and gynecology, and dermatology. These boards are to be conducted by standards for such certification developed by the Council on Medical Education and Hospitals. Moreover, the American Medical

¹ MacNider, W. de B. The Resistance of Regenerated Cells. *Science* (supplement) **78** 6 (Nov. 24) 1933.

Association, through its directory and in other ways, proposes to make available to the medical and general public the names of those who have satisfactorily met the qualifications established in this way. These measures should do much to lift roentgenology out of the welter of low grade and commercial practice into which it seemed inclined to tumble.

Association News

THE CLEVELAND SESSION Cleveland Hotels

The Subcommittee on Hotels of the Local Committee on Arrangements has furnished the list of Cleveland hotels and rates for rooms, which may be found below. On advertising page 38 of this issue of THE JOURNAL may be found this list together with an application form that may be used to secure reservations through the Subcommittee on Hotels. The form that is printed in the advertising pages may be clipped and when properly filled in, should be sent at once to Dr. Hubert C. King, Chairman of the Subcommittee on Hotels of the Local Committee on Arrangements, 1604 Terminal Tower, Cleveland, Ohio.

If those who expect to attend the annual session of the American Medical Association will send in their applications at the earliest possible time there should be no difficulty encountered in securing satisfactory accommodations. Applicants for reservations are especially requested to include a second and a third choice in order that good accommodations may be assured if the desired reservation cannot be had at the hotel of preference.

NOTE—A number of the lower priced single rooms are equipped with double beds. Many of these rooms are available for occupancy by two persons at only \$1 more than the single rate.

MEDICAL BROADCASTS

National Broadcasting Company

The American Medical Association broadcasts on a coast-to-coast network each Monday afternoon from 4 to 4:15, Central standard time (5 o'clock, Eastern standard time, 3 o'clock, Mountain standard time, and 2 o'clock, Pacific standard time). The next three broadcasts will be as follows:

February 26 Health Superstitions Morris Fishbein M.D.
March 5 Dangerous Drugs Paul Nicholas Leech Ph.D.
March 12 Consistent Inconsistencies R. G. Ireland M.D.

Columbia Broadcasting System

The Association broadcasts on a western network of the Columbia Broadcasting System each Thursday afternoon on the Educational Forum from 4:30 to 4:45, Central standard time. The next three broadcasts will be as follows:

March 1 Frontiers of Medicine Morris Fishbein M.D.
March 8 Keeping Your Health W. W. Bauer M.D.
March 15 The Health of the Schoolchild W. W. Bauer M.D.

Station WBBM

The American Medical Association broadcasts on Tuesday mornings from 8:55 to 9 o'clock, Central standard time, over Station WBBM (770 kilocycles, or 389.4 meters). The subject for Tuesday, February 27, is "Botulism."

Medical News

(PHYSICIANS WILL CONFERR A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION, PUBLIC HEALTH, ETC.)

ARIZONA

Survey of School Children—The state board of health, in conjunction with the Civil Works Administration, will make a survey of all children in the elementary schools to determine the amount of malnutrition present, the prevalence of tuberculosis, and the number of crippled children in the state. In addition information will be gathered to assist in a program to eliminate trichinosis and other diseases endangering the health of children attending the public schools.

ARKANSAS

Society News—The Mississippi County Medical Society was addressed in Bluffville, January 2, by Dr. Nona B. Ellis, Wilson, on "Importance of Urinalysis."—At a meeting of the Conway-Pope-Yell County Medical Society in Dardanelle, January 18, Dr. George R. Siegel, Clarksville, discussed "Endocrine Therapy in the Climacteric."—Dr. Dewell Gann Jr., Little Rock, spoke on "Transillumination of Cancer of the Breast" before the Lonoke County Medical Society in Lonoke, January 10.—At a meeting in El Dorado, January 9, under the auspices of the Union County Medical Society, the Tri County Medical Society was converted into the Fifth Councilor District Medical Society, including Union, Ouachita, Columbia, Calhoun, Lafayette and Dallas. Speakers were Drs. Leonce J. Kosminsky, Texarkana, on "Medical Organization of Today," J. H. Eugene Rosamond, Memphis, "Practical Points in the Diagnosis and Treatment of Infantile Paralysis," and Robert L. Sanders, Memphis, "Surgical Lesions of the Gallbladder."—Speakers before the Southeast Arkansas Medical Society at Lake Village, January 15, were Drs. Alan G. Cazort, Little Rock, and William H. Hamley, Lake Providence, La., on allergic diseases and organization of the district medical society, respectively.

CALIFORNIA

Dr. Elliott Gives Scripps Lectures—Dr. Charles A. Elliott, professor of medicine, Northwestern University School of Medicine, Chicago, delivered the annual Scripps Metabolic Clinic lectures at La Jolla and San Diego, January 11-13. His subjects were "Management of Hepatic Disease," "Management of Edema in General Practice," and "Hyperthyroidism and Psychoneurosis." Dr. Elliott also conducted clinics.

Enforce Law on Wiping Rags—At a meeting, January 2, the California State Department of Health directed that the law which provides for the sterilization of wiping rags be

enforced Shipments of wiping rags from foreign countries must be sterilized immediately on arrival, before sale and distribution. This action was taken in view of the fact that large quantities of soiled rags are received in this country from Oriental ports, chiefly Japan, it was stated.

Society News—Dr Eberle Kost Shelton, Santa Barbara, addressed the Hollywood Academy of Medicine, February 15 on "The Pituitary Growth Hormone."—At a meeting of the Alameda County Medical Association, February 19, speakers were Joe G Sweet, LL D, San Francisco, on "Outlook on Malpractice Litigations," Dr Hubert N Rowell, "Testamentary Capacity," and Earl G Warren, LL D, Ashland, "The Medical Witness."—Dr Nathaniel G Alcock Iowa City, was among the speakers before the Los Angeles Surgical Society, February 9, on "Treatment of Kidney Tumors of Childhood."

COLORADO

Valley Meeting at Pueblo—The annual meeting of the Arkansas Valley Medical Association will be held in Pueblo, March 10. The tentative program includes the following speakers:

Dr George B Eusterman Rochester Minn peptic ulcer
Dr Ray M Balyeat Oklahoma City allergy other than asthma and hay fever
Dr Gerald B Webb Colorado Springs (subject not announced)
Dr Edward B Liddle Colorado Springs treatment of anterior and posterior urethritis and complications
Dr Edgar C Webb Canon City eye examinations of school children
Dr Josephine N Dunlop Pueblo amebic dysentery
Dr Thomas D Cunningham Denver diagnosis of allergic manifestations
Dr George W Bancroft Colorado Springs surgery

All members of the state medical society and the societies of adjoining states are invited.

Three New Societies Organized—Announcement is made of the organization of three new societies in Colorado. At a meeting, January 30, the Washington and Yuma Counties Medical Society was created with Drs Clayton J Bennett, Yuma, president, Marvel L Crawford, Akron, vice president, and Laurence D Buchanan, Wray, secretary. The Clear Creek Valley Medical Society was organized in Golden, February 1, with the following officers: president, Dr Roger G Howlett, Golden, vice president, Dr George P Bailey, and secretary, Dr Orlo R Sunderland, Edgewater. At a meeting in Brighton, February 3, the Adams County Medical Society was founded with Dr John C McCann, Brighton, president, Dr Ralph D Elmore, Eastlake, vice president, and Dr John C Stucki, Brighton, secretary. Temporary charters have been granted to these societies, pending issuance of permanent charters next September at the annual session of the state medical association.

CONNECTICUT

Institute for Midwives—The Connecticut State Health Department conducted its tenth annual institute for the education of midwives in New Britain, Nov 17, 1933. Topics discussed included relation of the health department to midwives, placenta praevia, relation of the physician to the midwife, and the mental attitude of the expectant mother.

Influenza or Food Poisoning?—What was at first thought to be an outbreak of food poisoning in November at the Grace Hospital, New Haven, is believed to have been an outbreak of grip with abdominal symptoms, following investigations by the health board. It was found that 120 people had partaken of a certain meal, November 8, and that the only article of food that had been consumed by them all was freshly cooked steak. About twenty persons of the hospital community became ill between twelve and twenty-four hours after eating this meal, with symptoms of nausea, vomiting and abdominal pain and, in a few cases, mild or moderately severe diarrhea. On the second or third day every one of the patients developed a red and edematous throat, typical of grip. Of fifty patients seen, eight were ill before the meal in question, twenty were ill at about the same time, that is, from one to four days after the meal, and twenty two were ill more than five days after eating the meal. Of the number who were ill, thirteen had not eaten this or any other meal in the hospital. One person who had eaten the meal was found to have been living in another hospital where a number of her associates were ill at the same time with what was diagnosed and treated as abdominal grip. One man who had eaten a meal as a test and who had become ill did not develop any of the respiratory signs or symptoms which the others had. It was concluded that there was not a single fact that could not be adequately explained on the basis of an outbreak of influenza whereas there were many features that could not be explained by a diagnosis of food poisoning.

DISTRICT OF COLUMBIA

Medical Bills in Congress—H R 7210, introduced by Representative Black, New York, and S 2407, introduced by Senator Shipstead, Minnesota, propose to license barbers in the District of Columbia. Section 2 of the bills provides that the practices authorized thereunder "when done for the treatment of physical or mental ailments or disease shall not constitute barbering." Persons licensed to practice medicine and surgery, osteopathy or chiropractic, commissioned medical or surgical officers of the United States Army, Navy or Marine hospital service, and registered nurses are, among others, exempted from the provisions of the bills.

ILLINOIS

Personal—Dr Albert C Baxter, Springfield, was recently presented with a silver beaver, emblem of noteworthy service in scouting, by the Abraham Lincoln Council of the Boy Scouts of America. The silver beaver is the highest award in boy scout work and is granted only by the National Council of Boy Scouts of America. Dr Baxter has been identified with the scout movement since its inception in central Illinois.

Medical Economics—Questionnaires have been issued to physicians in Pulaski, Franklin, Livingston and Winnebago counties by the committee on medical economics of the state medical society in an effort to learn how great a change has occurred in the work done, the income derived between the years 1929 and 1933, and the amount of charity work done. Charity work must consist of work for which no charge is made and must be differentiated from work for which a fee is charged but is uncollectible. These four counties were selected because it was believed they represented, respectively, typical farming in southern Illinois, mining and farming in central Illinois, and industrial development in northern Illinois.

Chicago

Dr Joslin to Address Medical Society—Dr Elliott P Joslin, clinical professor of medicine, Harvard University Medical School, Boston, will address the Chicago Medical Society, February 28, in the Medical and Dental Arts Building "The Diabetic of the Future and His Problems" is the subject of Dr Joslin's lecture. A dinner in his honor will precede the meeting.

Medical Reserve Meeting—Major General Robert U Patterson, surgeon general of the U S Army, Washington, D C, will be the speaker at the annual dinner of the medical chapter, Reserve Officers' Association, at the Army and Navy Club, March 5. Dr Patterson will discuss the "Reserve Officers' Corps of the U S Army." All physicians, especially those who served in the World War, are urged to attend the dinner. Arrangements may be made with Lieut Col Stanley W Clark, dental corps reserve, secretary, or Lieut Col George T Jordan, medical corps reserve, president.

Dental Meetings on Medical Relations—The clinical problems of dentistry and medicine will be treated in sessions on medical relations at the annual midwinter meeting of the Chicago Dental Society in the Stevens Hotel, February 27-March 1. Participating in this phase of the program will be:

Dr Harry A Singer Diseases of the Stomach
Dr Richard H Jaffe Leukemias
Drs Lewis J Pollock and Harry A Paskind Neurology
Dr Hayes E Martin New York Differential Diagnosis of Benign and Malignant Tumors of the Oral Cavity
Dr James Persons Simonds and Carroll W Stuart, DDS Malignant Tumors of the Head and Neck
Drs Harry E Mock Frederick W Merrifield and Edward L Jenkins Traumatic Injuries of the Head and Neck
Drs Francis E Senechal Edward A Oliver and Joseph E Schaefer, Dermatology and Diseases of the Head and Mouth

While these problems will be discussed from the medical aspect, the contingent dental relationship will also be considered.

INDIANA

District Meeting—Dr Ernest M Conrad, Anderson, was elected president of the Eighth District Medical Society, Anderson, December 7 succeeding Dr Henry W Gante, Anderson, who had held the office since 1924. Muncie was chosen as the place for the 1934 session. The Madison County Medical society acted as host for this meeting at which speakers included Drs Byrl R Kirklin and Frank C Mann, both of Rochester, Minn, on "X-Ray Diagnoses of Digestive Disturbances" and "Liver Diseases," respectively.

Personal—Dr Bayard G Keeney, Shelbyville, has been appointed health commissioner of Shelby County.—Dr Noah A Rocky Fort Wayne has been named health officer for Allen County.—Dr Christian A Dresch, Mishawaka, has retired from active practice.—Dr John C Carney has been

appointed health officer of White County, succeeding Dr Arthur B Cray, who held the position ten years—Dr Sayers J Miller, assistant medical adviser at Purdue University, has been named acting director of student health service, succeeding the late Dr Oliver P Terry

IOWA

Memorial to Dr Prentiss—A bronze bust of Dr Henry James Prentiss, late professor and head of the department of anatomy, histology, embryology and neuro anatomy, University of Iowa College of Medicine, Iowa City, was placed in the medical library of the university, Nov 6, 1933, the gift of the Alumni Association of the college of medicine. Three friends of Dr Prentiss, Drs Nathaniel G Alcock, Iowa City, Verne C Hunt and Charles J Rowan, Santa Monica, Calif, presented the pedestal on which it stands. Dr Prentiss was also director of the laboratories of histology and embryology of the college of medicine. He died, May 17, 1931.

Society News—At the annual midwinter meeting of the Upper Des Moines Medical Society in Emmetsburg, January 23, speakers included Drs Fred L Knowles, Fort Dodge, on reduction of fractures of the neck of the femur double pin method, and Joseph B Priestly, Des Moines, surgical management of peptic ulcer—Dr Morris Fishbein, editor of THE JOURNAL, Chicago, will address the Linn County Medical Society, March 8 on "Current Trends in Medical Practice." Dr Walter L Bierring, Des Moines, President-Elect, American Medical Association, will discuss the paper

KANSAS

Personal—Dr Carl M Vernillion, Pratt has been designated health officer of Pratt County, succeeding Dr Marshall F Christmann—Dr William K East has been named health officer of Atchison and Atchison County—Dr Henry S Dreher, Luray, has been named health officer for Russell County.

Society News—Dr William P Callahan, Wichita discussed tumors of the breast before the Ford County Medical Society, Dodge City, January 12—Dr Frank L Rector, Lyndon, Ill, discussed "Present Day Cancer Problems" before the Wyandotte County Medical Society, January 16 and Dr Ralph G Ball, Manhattan, "Diseases of the Suprarenal Gland with Research Studies," February 6.

KENTUCKY

Personal—Dr Leonard A Crosby, Williamsburg, has been named health officer of Todd County, succeeding Dr Thomas J La Motte, who will engage in graduate study at Tulane University of Louisiana School of Medicine, New Orleans—Dr John H Blackburn, Bowling Green, has been appointed a member of the state board of health to succeed Dr Laurence F Minish, Frankfort. Dr E Murphy Howard Jr, Harlan, and Carl Johnson, D O, Louisville, were reappointed to the board.

Bills Introduced—H 533 to liberalize those provisions of the workmen's compensation act requiring an employer to furnish medical, surgical, hospital and nursing service to an injured employee, proposes to increase the limit of an employer's liability to \$100 for hospital treatment and \$150 for medical surgical and nursing treatment. H 434 proposes to authorize the sterilization of inmates of state hospitals for the insane or feeble-minded. S 254 proposes to reorganize the executive branches of the state government. Among other things, it proposes to create a department of health, to exercise all administrative functions of the state in relation to public health, sanitation and the prevention and control of communicable diseases. It proposes, too, to create a division of licensing in the department of health to assume all functions with respect to the examining and licensing of applications for professional licensure, now vested in the state board of health, the board of examiners of nurses, the board of chiropractic examiners, the board of dental examiners, the Kentucky Pharmaceutical Association and the board of pharmacy.

MASSACHUSETTS

Personal—Dr George M Sullivan has resigned as superintendent of the Pondville Hospital, Wrentham after four years' service. Dr George L Parker has been appointed to succeed Dr Sullivan.

Dr Martin Honored—Dr George Forrest Martin, who recently resigned as senior surgeon of the Lowell General Hospital, Lowell, after forty years service, was honored at a dinner by associates, December 7. Dr Chester Stoye Baker was toastmaster. In addition to Dr Martin speakers included

Drs Archibald R Gardner, his successor as senior surgeon, Howard W Jewett, John H Nichols, Tewksbury, and Mr John F Sawyer. Dr Martin will continue as a member of the board of trustees of the hospital and as a consultant.

Medical Pageant—The third annual medical historical pageant, given by the students of Tufts College Medical School and directed by Dr Benjamin Spector, associate professor of anatomy, was presented in conjunction with the reception to the entering class in Boston, Nov 14, 1933. Students participating in these pageants are usually taken from the third and fourth year classes. This year's presentation depicted the following characters:

From Egyptian medicine 4500 1000 B C Imhotep Antep Amenemhat Khuy and Kekanacht
From Greek temple medicine 1200 B C 130 A D Aesculapius Hippocrates Chrysiptus Aretaeos
From Greek philosophical medicine Plato (428 347 B C) Aristotle (384 322 B C)
From Renaissance medicine Roger Bacon (1214 1284)
From Modern Medicine Lavoisier (1743 1794) Pasteur (1794 1826) Jenner (1749 1823) Laennec (1781 1826), Darwin (1809 1882) Virchow (1821 1902) Roentgen (1845 1923)

Appropriate historical remarks were made between the appearances of the characters. There was also an exhibition of classical texts of the characters portrayed in the pageant by Mr James F Ballard, director Boston Medical Library. The presentation of the medical pageant was introduced at Tufts in 1930 by Dr Spector.

MICHIGAN

Society News—Dr George K Fenn, Chicago, discussed clinical and experimental considerations of the coronary circulation before the Calhoun County Medical Society in Battle Creek, January 9—Dr Frederick H Falls, Chicago discussed "Pernicious Vomiting of Pregnancy" at a meeting of the Wayne County Medical Society, Detroit, February 5—At a meeting of the Monroe County Medical Society in Monroe, January 18, Drs Lawrence H Carleton and James Clark Moloney, Detroit spoke on "Relief of Bladder-Neck Obstruction" and "Lumbar Puncture," respectively.

Emergency Hospitalization—Injured persons able and willing to pay for hospital care will be taken to private institutions in the future, in accordance with a recent order of John P Smith, police commissioner of Detroit. Persons becoming ill in public places will be taken to the Receiving Hospital unless they request to be taken to another hospital or to their own homes, provided the distance of the latter is not appreciably greater. On the recommendation of a physician or if it appears necessary to the officer in charge because of the seriousness of the injury or illness, however, the person shall be taken to the nearest hospital. This arrangement is the result of several conferences of the commissioner with representatives of the Wayne County Medical Society and the Detroit Hospital Council. It is believed that the enforcement of the order will save time in emergencies, long hauls and expense to the city, and will give mental and physical satisfaction to injured citizens. In addition the practice of rushing injured persons to a city hospital against their wishes will be abolished.

MISSISSIPPI

Bills Introduced—S 236 proposes to amend the privileged communications statute by providing that it shall not apply in criminal cases in which the mental or physical condition of the patient is material in determining the innocence or guilt of the accused or the extent of his guilt or to any civil case in which the mental or physical condition of the patient is put in issue by the patient or by his personal representative, heirs or distributees. S 248 proposes to extend the period during which an action for malpractice may be brought after the occurrence of the cause of action from one to three years.

MISSOURI

Medicomilitary Symposium—The Kansas City Southwest Clinical Society and the medical department, seventh corps area, U S Army, are cooperating in a spring medicomilitary symposium at Kansas City General Hospital, March 12-17. Sessions will be given over to a consideration of the various aspects of heart disease, tuberculosis, diseases of the digestive system and syphilis. Evening programs will be presented by regular army officers from the seventh corps area, subjects selected for discussion will include the "Army's Job in the CCC Activities," "Mechanization of Modern Armies," "The Medical Regiment," "Modern Conceptions of Dietary Needs," "Aviation in Medicine," and "Smallpox and Vaccination." Three topics will occupy one afternoon session: water, the medical department and joint operations of the army and navy.

in overseas expeditions Tuesday evening, March 13, will be devoted to a joint meeting of the Jackson and Wyandotte County medical societies, and Friday evening to that of the Kansas City Academy of Medicine, when the speaker will be Dr Charles A Doan, Columbus, Ohio, on "Clinical Implications of Experimental Hematology." The Kansas City Dermatological Society will present a symposium on syphilis.

NEW JERSEY

Bill Introduced—S 136, to amend the law providing liens for hospitals treating persons injured through the fault of others, proposes to authorize similar liens for physicians and surgeons.

NEW YORK

Bills Introduced—A 626, to amend the law providing for the exemption of hospital ambulances from registration fees, proposes to limit such exemption to ambulances used exclusively to carry sick or injured persons. A 715, to amend those provisions in the medical practice act relating to osteopathy, proposes (1) to designate osteopaths as osteopathic physicians and (2) to provide that 'a license to practice osteopathy shall not entitle the holder to perform any surgical operation involving incision or the opening of a natural body cavity, for the removal of cancer or other tumor, for the amputation of an extremity or appendage, or for the removal of any gland or organ, or part thereof, of the human body, nor shall such license permit the holder thereof to administer drugs, except narcotics, anesthetics, antiseptics, vaccines and antitoxins.' A 716 proposes to give hospitals treating persons injured through the negligence of others liens on all rights of action, suits, claims, judgments or settlements accruing to the injured person by reason of their injuries. A 728, to amend the workmen's compensation act, proposes, in effect, to make compensable all occupational diseases contracted in any employment covered by the act. A 740 proposes to prohibit hospitals, supported wholly or partly at public expense, from charging any fee for medical dental or pharmaceutical services rendered while operating clinics to which the public is invited. A 744 proposes to establish in each public welfare district a central bureau to which persons desiring medical, surgical or other treatment in clinics are to apply. This bureau, after investigation, is to issue a permit to the applicant entitling him to treatment by a clinic located in the hospital that is nearest the place of his residence.

New York City

Safety Conference—The fifth annual Greater New York Safety Conference will be held at the Hotel Pennsylvania March 6-7. Among speakers will be Dr Hart Ellis Fisher, Chicago, on "The Problem of the Return to Work Employee," Dr William R Redden, New York, "First Aid in Schools," and Philip Drinker, ChE, Boston, "Protection of Workmen Against Dust Inhalation."

Hospital News—The Metropolitan Hospital Alumni Association was recently organized with Drs Samuel Schechter as president and Abraham P Matusow as secretary. A physical therapy department was opened at New York Polyclinic Medical School and Hospital December 11. The department is in the new clinic building of the hospital and is under the direction of Dr Richard Kovacs.

Personal—Dr Samuel J Kopetzky was recently made a Knight of the Legion of Honor by the French government for his collaboration on medical work with French scientists. Dr Charles J Sutro has been awarded the Mr and Mrs Frederick Brown Orthopedic Research Fellowship offered through the Hospital for Joint Diseases. It includes a stipend of \$2400. Dr Sutro has been a member of the hospital staff for two and a half years. Dr Peter F Amoroso has been appointed second deputy commissioner of corrections among other duties he will direct the prison hospitals. Friends of Dr Francis Huber presented to him an illuminated testimonial describing their appreciation of his work as physician and teacher on his eightieth birthday, February 2.

Impostor Convicted—It is reported that Samuel Greenberg, who practiced medicine for more than a year with a forged regent's diploma and county certificate and who used the address of Dr Samuel Greenberg of Brooklyn to obtain a genuine registration certificate, was sentenced December 21 to six months in the workhouse after he pleaded guilty to practicing without a license. Sentence was suspended in consideration of the fact that he made a complete confession at the time of his arrest. It appears that Greenberg worked himself into the good graces of a New York physician and asked to be allowed to have mail delivered at his office. Later he wrote to the state board of medical examiners giving the

real Dr Greenberg's address and requesting that as he was moving from Brooklyn to New York his annual registration certificate be mailed to him at the new address. After this the spurious "Dr" Greenberg disappeared. Investigators of the office of Assistant Attorney General Sol Ullman found him practicing medicine at 1280 Walton Avenue, The Bronx, and arrested him, Oct 18, 1933, on a charge of practicing without a license. Greenberg then implicated a Filipino artist, Julian Noveno, who, he alleged, forged the state and county documents. Noveno was indicted on a charge of forging medical credentials.

OHIO

Centennial Celebration at Ohio State University—The one hundredth anniversary of Ohio State University College of Medicine, Columbus will be celebrated with three days of reunions, clinics, addresses and exhibits, March 1-3. Tracing its history to the Willoughby Medical College established in 1834 at Willoughby, Ohio, the present school of medicine is the result of a series of mergers and consolidations, which have brought together the Willoughby College, Starling Medical College, Columbus Medical College, Ohio Medical University and Starling-Ohio Medical College. The program will open Thursday morning, March 1, with clinics in medicine and surgery at University and St Francis hospitals by Drs Francis Carter Wood, New York, Gatewood, Chicago, and Bernard H Nichols, Cleveland, among others. Laboratory demonstrations, exhibits and reenactments of historical events by students and faculty will be held in the afternoon. A dinner will be given for the faculty and guests in the evening, followed by a meeting in University Chapel. Dr John H J Upham, dean of the School of Medicine, will preside at this session and speakers will be

Dr Francis R Packard, Philadelphia, "Earliest Development of Organized Medical Education in This Country,"
Dr Jonathan Forman, Columbus, "History of the College of Medicine,"
George W Rightmire, LL.D, president, Ohio State University, Columbus, "The Place of Medical Education in the State University."

A special convocation will be held in the morning of March 2, at which Dr Henry S Houghton, Chicago, will speak on "The Challenge of the Future to Medical Education." Following about sixty class reunions at the noon hour, addresses will be presented by Drs Francis Carter Wood, on cancer, and Edward Francis Washington, D C, on tularemia. Various medical fraternities will hold banquets in the evening. The morning of Saturday, March 3, will be devoted to surgical clinics directed by Drs Gatewood, Mont R Reid, Cincinnati, and Roy D McClure, Detroit, and medical clinics by Frank A Hartmann, PhD, Buffalo, and Dr Torald H Sollmann, Cleveland. Dr George T Pack, New York, will also deliver an address on "Irradiation Therapy" during the morning. Following a luncheon at University Hospital for alumni and guests, clinics will be conducted by Drs Robert M Zollinger, Boston, Robert A Moore, Raymond L Pfeiffer and Samuel T Mercer, New York. In the evening an Alpha Omega Alpha initiation and supper will be given, followed by the first annual Alpha Omega Alpha public address, presented by Dr Charles P Emerson, former dean, Indiana University School of Medicine, Indianapolis. In connection with the celebration, an exhibit of medical and dental equipment used in Ohio during the past century has been arranged. Invitations are being issued to alumni of the school and its predecessors, but the profession generally is invited to attend the program of activities, the university announces. Dr Ernest Scott is general chairman of the centennial observance.

PENNSYLVANIA

Society News—Dr Roy Wesley Scott, Cleveland, addressed the Washington County Medical Society, February 9, on "Modern Aspects of Cardiovascular Diseases from the General Practitioner's Standpoint." Dr Bernard H Nichols, Cleveland, addressed the Pittsburgh Urological Association, February 12, on "The Art of Pyelographic Interpretation." Dr Curtis C Mechling addressed the Pittsburgh Pediatric Society, February 16, on "Common Disorders of the Rectum and Anus and Their Management." Speakers before the Pittsburgh Academy of Medicine, February 13, were Drs Frank W Donley, on "Trichinosis," Evan W Meredith, "Pyloric Stenosis," and David Silver, "Physical Diagnosis and Significance of Sounds In and Near Joints." Dr George B Stull, Harrisburg, delivered his address as retiring president of the Dauphin County Medical Society, January 2, on gallbladder disease. Dr Ford A Miller, Philadelphia, addressed the Delaware County Medical Society, Chester, February 8 on "Bleeding in Labor." Dr Jesse O Arnold, Philadelphia, addressed the Medical Society of Franklin County, January 16, on obstetrics.

Philadelphia

University News—Temple University celebrated its fiftieth anniversary during the week of February 11-17. The medical school as its part offered an intensive course of lectures, clinics and demonstrations to evaluate the present status of the medical art and its basic sciences. All regularly qualified physicians in New York, New Jersey, Maryland, Delaware and Pennsylvania were invited. Dr. Lewellys F. Barker, Baltimore, delivered an address on "Medicine in Soviet Russia" before the medical department, February 14. The honorary degree of doctor of science was conferred on Drs. Royal S. Copeland, New York and George E. de Schweinitz, Philadelphia, at the midyear commencement, February 15.

TEXAS

Health at El Paso—Telegraphic reports to the U. S. Department of Commerce from eighty-six cities with a total population of 37 million, for the week ended February 10, indicate that the highest mortality rate (28.2) appeared for El Paso and that the rate for the group of cities as a whole was 12.2. The mortality rate for El Paso for the corresponding week of 1933 was 9.6 and for the group of cities, 11.8. The annual rate for eighty-six cities was 12.5 for the six weeks of 1934, as against a rate of 12.7 for the corresponding period of the previous year. Caution should be used in the interpretation of these weekly figures, as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have a large Negro population may tend to increase the death rate.

Sam Kaplan Convicted—The Texas State Board of Medical Examiners reports the conviction in the criminal court of Harris County, Nov. 29, 1933, of "Dr. Sam Kaplan who had been practicing medicine in Houston without a license. He was sentenced to pay a fine of \$50 and costs and serve one day in jail, escaping with this light sentence because he promised to discontinue practicing until he obtains a license. Kaplan's record indicates that he was graduated in 1917 from the St. Louis College of Physicians and Surgeons, one of the schools involved in the Missouri diploma mill scandal. He was never licensed to practice, having failed at examinations in Missouri five times in 1921, 1922 and 1923. In 1924 when the Missouri schools were investigated it was shown that Kaplan was associated with Reuben Adcox in those operations (THE JOURNAL, July 5, 1924, p. 46). Other records of the American Medical Association indicate that he was connected with the Connecticut diploma mill scandal and also with the so-called Oriental University of Washington, D. C., another fake school. The Texas board reported that Kaplan applied for admission to its examinations, Nov. 21, 1933, but was rejected because of his inability to prove that he was 'of good moral character' and because of his conviction in a federal court in Washington of conspiracy to use the mails to defraud in connection with the 'Oriental University'."

VIRGINIA

Bills Introduced—A bill introduced in the house of delegates, February 9, by Mr. Stephens, and referred to the committee on finance, proposes to require physicians to obtain annual "revenue licenses" from the state. Physicians licensed for less than five years are to pay \$15 annually, while physicians licensed for more than five years are to pay \$25, but no physician whose gross annual income is less than \$500 is to pay more than \$15. A bill introduced in the house of delegates, by Mr. Coleman, February 8, and referred to the committee on general laws, proposes to create a board of barbering and to regulate the practice of barbering.

WASHINGTON

Personal—Dr. Francis M. Carroll has been appointed health officer of Seattle to succeed Dr. John S. McBride, who died Nov. 15, 1933. Dr. Carroll served a term as health officer about thirty years ago—Dr. Dale O. Nugent was elected mayor of Centralia recently.

Annual Surgical Clinics—The Seattle Surgical Society held its annual clinics, February 16-17, at Harbor View Hospital. At the annual dinner Saturday evening, Prof. Charles E. Martin, Ph.D. of the University of Washington, made an address on "Present Trends in European Politics."

Society News—Dr. Clarence W. Brunkow, Portland, addressed the Yakima County Medical Society, Yakima, December 11, on surgery in children—Drs. Hulett J. Wickoff and Harold E. Nichols, Seattle, addressed the Chelan County Medical Society in December at Wenatchee on injuries to

the back and roentgen diagnosis, respectively—Drs. Charles R. McColl and Glenn M. Steele, Tacoma, addressed the Pierce County Medical Society, Tacoma, December 12, on "Clinical Application of Laboratory Medicine" and "Office Procedure in Gynecology," respectively—Dr. Horace J. Whitacre, Tacoma, among others, addressed the Snohomish County Medical Society, Everett, December 6 on federal unemployment medical relief—Dr. Robert F. E. Ster, Spokane among others addressed the Walla Walla Valley Medical Society, Walla Walla, December 14, on new laboratory technics in relation to diagnosis and treatment of disease.

GENERAL

Mortality Rates for Large Cities in 1933—Eighty-six large cities in the United States which report their mortality rates weekly to the U. S. Department of Commerce had an average death rate of 11 per thousand of population during the calendar year 1933 according to figures in *Public Health Reports*. Washington, D. C., and Memphis, Tenn. had the highest rates (16), New Orleans and Nashville, Tenn., followed with 15.6 and 15.1, respectively. The lowest rate appeared for Detroit (6.9), which was followed by Akron, Ohio and South Bend, Ind., with 7.3 and Milwaukee, 8. The provisional infant mortality for 1933 for the eighty-six cities was 53, the actual number of deaths under 1 year being 29,776. The rate for 1932 was 55. The lowest infant mortality rate appears for Fort Wayne, Ind., with 26, the next in order were Tacoma, Wash. with 28, Long Beach, Calif., and Des Moines, Iowa, each of which had a rate of 30.

Congress Limits Medical Service for CWA Employees—Medical and hospital service and disability and death benefits for employees of the Federal Civil Works Administration have been limited by act of Congress, approved February 15 to cases of injury by accident causing damage or harm to the physical structure of the body. Diseases that naturally result from such injuries entitle injured employees to medical and hospital services and disability and death benefits. Other diseases do not even though they arise out of and in the course of employees' discharge of their duty. The change seems to work no change with respect to medical and hospital services except to limit them to cases of traumatic injury as defined by the act and diseases resulting from such injuries. Employees who suffer from other diseases will have to look for medical and hospital relief to the state or local relief agencies to the Federal Emergency Relief Administration or to the charity of physicians.

Southeastern Surgeons Meet in Nashville—The fifth annual assembly of the Southeastern Surgical Congress will be held in Nashville, Tenn., March 5-7, under the presidency of Dr. Willis C. Campbell, Memphis. Among speakers who will address the sessions are:

- Dr. William Wayne Babcock, Philadelphia: Postoperative Abdominal Complications and Their Management
- Dr. Chevalier Jackson, Philadelphia: Carcinoma and Sarcoma of the Esophagus
- Dr. John F. Erdmann, New York: Tumors of the Breast
- Dr. Joseph F. McCarthy, New York: Developments in Operative and Diagnostic Instrumental Urology
- Dr. George W. Crile, Cleveland: Five Points in Surgery of the Gall bladder and Ducts
- Dr. Paul G. Flotow, Seattle: Vascular Diseases of the Extremities and Their Treatment
- Dr. George H. Semken, New York: Some Experiences in Cancer Surgery
- Dr. Arthur E. Hertzler, Halstead, Kan.: Reaction of Tissues to Injury in Relation to Wound Healing and Drainage
- Dr. John J. Moorhead, New York: Precepts in Traumatic Surgery
- Dr. Melvin S. Henderson, Rochester, Minn.: Derangements of the Knee Joint
- Dr. Fred H. Albee, New York: Bacteriophage in Wound Treatment

The annual banquet will be held at the Andrew Jackson Hotel, Tuesday evening, with Dr. Perry Bromberg, Nashville, as toastmaster and Dr. Stewart R. Roberts, Atlanta, as the speaker.

Society News—At the seventh annual meeting of the Dermatological Conference of the Mississippi Valley in Chicago, January 20, with the Chicago Dermatological Society as host, there were representatives from St. Paul, Minneapolis, Rochester, Ann Arbor, Detroit, St. Louis, Oklahoma City, Pittsburgh, Cincinnati, Houston, Texas, and other cities. Thirty-four patients with uncommon diseases were shown at the clinical demonstration in the afternoon—The sixty-seventh annual meeting of the American Otological Society will be held at the Claridge Hotel, Atlantic City, April 6-7—Dr. Edwin L. Perkins, Sioux Falls, S. D., was elected president of the Sioux Valley Medical Association at its annual meeting in Sioux City recently, succeeding Dr. Sidney A.

Slater, Worthington, Minn. Dr Charles C Telleston, Wynot, Neb., was reelected vice president, and Dr Ludwig L. Sogge, Windom, Minn., named vice president to succeed Dr Perkins. Dr William Roscoe Jepson, Sioux City, was reelected secretary, and Dr Walter R. Brock, Sheldon, Iowa, treasurer.

Medical Grants of National Research Council—The committee on grants-in-aid of the National Research Council announces the following grants in the field of the medical sciences:

Dr Garland Howard Bailey, associate professor of immunology, Johns Hopkins University School of Hygiene and Public Health, Baltimore, on heterophile antigens of bacteria and plant and animal tissues.
Raymond L. Garner, Ph.D., assistant in medicine, Johns Hopkins University School of Medicine, Baltimore, enzymatic liquefaction of clotted human blood.

Dr Ralph W. Gerard, associate professor of physiology, University of Chicago, activity of nerve tissue and the central nervous system.
Dr Balduin Lucke, professor of pathology, University of Pennsylvania School of Medicine, Philadelphia, a neoplastic disease of the common leopard frog, *Rana pipiens*.

Drs John R. Paul, assistant professor of medicine, and James D. Trask, associate professor of pediatrics, Yale University School of Medicine, comparison of different strains of poliomyelitis virus.
Arthur H. Smith, Ph.D., associate professor of physiological chemistry, Yale University School of Medicine, the influence of various inorganic ions upon the body weight and blood changes of experimental animals.

The National Research Council will consider further requests for research assistance later in the spring. Applications, presented on forms which will be furnished by the secretary of the committee on grants-in-aid, must be on file with the committee by March 15. The address of the council is 2101 Constitution Avenue, Washington, D. C.

Physical Therapy Meeting—The midwestern section of the American Congress of Physical Therapy will hold its spring session, March 13, in Indianapolis. The afternoon session will be held at the Indiana University School of Medicine, and the evening meeting at the Athenaeum. The following program has been announced:

Some Problems in Physical Therapy. Dr Albert F. Tyler, Omaha, president of the American Congress of Physical Therapy.

Treatment of Precancerous Lesions of the Face. Dr Disraeli Kobak, assistant clinical professor of physical therapy, Rush Medical College, Chicago.

Experimental and Clinical Observations on the Use of Irradiated Ergosterol. Carlos I. Reed, Ph.D., assistant professor of physiology, University of Illinois College of Medicine.

Cancer of the Hand (demonstration clinic). Dr Edwin N. Kame, associate in medicine, Indiana University School of Medicine, Indianapolis.

Physicochemical Basis of Physical Therapy. Dr Reinhard Beutner, professor of pharmacology, University of Louisville School of Medicine.

A Newer Conception of the Action of Infra-Red Radiation in Upper Respiratory Infections. Dr Abraham R. Hollender, instructor in otorhinolaryngology, University of Illinois College of Medicine.

Physical Energies in the Diagnosis and Treatment of Cancer of the Breast. Dr Argus David Willmoth, Louisville.

An Electrosurgical Method for Obliterating the Gallbladder. Dr Max Thorck, professor of surgery, Cook County Graduate School of Medicine, Chicago.

Physical Therapy in the Rehabilitation of the Disabled. Dr John Stanley Coulter, associate professor of physical therapy, Northwestern University Medical School, Chicago.

Medical Bills in Congress—Changes in Status H. R. 1766 has been reported to the House, without amendment, with a recommendation that it pass (H. Rept. 706). The bill provides medical services after retirement on annuity to former employees of the United States disabled by injuries sustained in the performance of their duties. H. R. 6663, the Independent Offices Appropriation Bill, has been reported to the Senate, with amendments (S. Rept. 294). The proposed amendments to the bill authorizing additional benefits to veterans were rejected by the Senate Committee on Appropriations. In the committee report, however, it is stated: "The statement was made by the chairman of the subcommittee having charge of the bill that he would give notice of a motion to suspend the rules for the purpose of offering certain amendments affecting veterans' benefits and the committee recommends that this motion be agreed to in order that veterans' legislation may be considered as amendments to the bill." H. R. 249 has passed the House, authorizing the House Committee on Labor to study the question of old age pensions and to recommend legislation establishing an old-age contributory pension system under the jurisdiction of the federal government if the committee deems such legislation appropriate. **Bills Introduced** S. 2526 introduced by Senator Long, Louisiana, proposes to pay an annuity to Frances Agramonte the widow of Dr Aristides Agramonte, a member of the Yellow Fever Commission. S. 2727 introduced by Senator Tidings, Maryland, proposes to provide medical services after retirement on annuity to former employees of the United States disabled by injuries sustained in the performance of their duties. S. 2753, introduced by Senator Walsh, Massachusetts, proposes to authorize the

Reconstruction Finance Corporation to make loans to publicly and privately controlled colleges, universities and other institutions of higher learning. H. J. Res. 255, introduced by Representative Wiedeman, Michigan, proposes to create a commission to formulate a permanent national policy with respect to benefits for veterans and dependents of veterans. H. J. Res. 257, introduced by Representative O'Malley, Wisconsin, proposes to authorize the Secretary of the Interior to arrange with the several states for the education, medical attention, relief of distress, and social welfare of the Indians. H. R. 7492, introduced (by request) by Representative O'Connell, Rhode Island, proposes to confer additional benefits on veterans. It proposes to reestablish service connections, presumptive and otherwise that were established prior to March 20, 1933, and that have since been severed. H. R. 7547, introduced by Representative Evans, California, proposes to continue the retirement pay received by emergency officers of the World War at the monthly rate that was being paid prior to March 20, 1933, if the disability for which the officer has been retired resulted from a disease or injury or aggravation of a pre-existing disease or injury incurred in line of duty during such service. H. R. 7552, introduced by Representative Hope, Kansas, proposes to grant pensions and increases of pensions to certain soldiers, sailors and certain nurses of the war with Spain, the Philippine insurrection or the China relief expedition, and their widows and dependents. Pensions for contract nurses are provided for under existing law. No pension is provided under existing law or in the proposed bill for contract surgeons. H. R. 7556, introduced by Representative Hastings, Oklahoma, proposes to protect workers in their old age, by authorizing a federal appropriation to be allotted to the several states to aid them in giving assistance to aged persons. H. R. 7594, introduced by Representative Lewis, Maryland, proposes to provide for publicity of executive and administrative rules, regulations and orders. H. R. 7598, introduced by Representative Lundeen, Minnesota, proposes to provide for the establishment of unemployment and social insurance. It would authorize the Secretary of Labor to establish forms of social insurance for the purpose of paying workers and farmers for loss of wages because of part time work, sickness, accident, old age or maternity. H. R. 7647, introduced by Representative Marland, Oklahoma, proposes to confer additional benefits on veterans. It provides that any World War veteran who is in need of hospitalization or domiciliary care and unable to defray the necessary expenses therefor shall be furnished hospitalization or domiciliary care in any Veterans' Administration facility, irrespective of whether the disability, disease or defect was due to service. A statement by the veteran that he is unable to defray the necessary expenses of hospitalization or domiciliary care must be accepted by the Administrator of Veterans' Affairs as conclusive evidence of that fact. H. R. 7661, introduced by Representative Connolly, Pennsylvania, proposes to permit radium to be accepted in payment of war debts due from Belgium and to authorize the President to provide by rules and regulations for the donation of the radium so received to hospitals, medical clinics and medical research organizations in the United States. H. R. 7830, introduced by Representative Boileau, Wisconsin, proposes to confer additional benefits on veterans. It would, among other things, authorize the Administrator of Veterans' Affairs, so far as he shall find that existing government facilities permit, to furnish hospitalization and necessary traveling expenses incident to hospitalization to veterans, without regard to the nature or origin of their disabilities. H. R. 7854, introduced by Representative Fish, New York, proposes to authorize the Reconstruction Finance Corporation to make loans to religious and educational institutions. H. R. 7964, introduced by Representative Jenckes, Indiana, proposes to prevent the adulteration, misbranding and false advertising of food, drugs and cosmetics.

FOREIGN

Society News—The seventh meeting of the German Society for Circulatory Research will be held in Bad Kissingen, April 16-17. Subjects to be treated are thrombosis and embolism, a theoretical lecture to be given by Prof. Ludwig Aschoff, Freiburg, and clinical lectures by Drs. Paul Morawitz, Leipzig, and Ludwig Nürnberger, Halle.

Centenary of Medical Society—The Norwegian Medical Society, Oslo, observed its one hundredth anniversary, November 5, the *Journal-Lancet* reports. Prof. Peter F. Holst, president of the society, presided and proposed a toast to King Haakon who, in his response, praised the society for its contributions to medical science. Thirty-one young physicians were given prizes ranging from \$500 to \$1,000 each made available annually through a bequest of the late Dr. Malthé.

New Building at London Medical School—King George V and Queen Mary officially opened new buildings for the medical school and pathologic institute at St. Mary's Hospital, London, December 12. The new buildings, which are continuous, are four stories high, with adequate accommodations for lecturers and laboratory work and in addition an underground garage, a swimming pool, a gymnasium and a squash rackets court. Dr. Charles M. Wilson is dean of the medical school, and Sir Almoth E. Wright, director of the pathologic institute. The buildings replaced were opened in 1852.

Personal—Dr. J. Sanchez Covisa, former president of the College of Physicians of Madrid and of the Spanish Society of Dermatology and Syphilology, has been appointed dean of the medical faculty of Madrid to succeed the late Dr. Sebastian Recasens.—Dr. Malcolm H. MacKeith, dean of the medical school of Oxford University, has been appointed dean of the new British Post-Graduate Medical School at Hammersmith. It is hoped that the school will be open to students the latter part of 1934.—Sir Leonard Rogers has retired as medical adviser to the secretary of state for India and president of the India Office Medical Board, having reached the age limit. He has been succeeded by Sir John W. D. Megaw, director general of the Indian Medical Service. Sir Leonard will continue his connection with the British Empire Leprosy Relief Association.—A surgeon, Mr. Godfrey Martin Huggins, has recently been chosen prime minister of Southern Rhodesia, Africa. A native of England, he has been in Rhodesia since 1910. He is consulting surgeon to the Salisbury Hospital.

Government Services

Food and Drug Seizures in January

The Federal Food and Drug Administration reports that seizure proceedings were instituted in January against 144 consignments of food and drugs and that twenty-three criminal prosecutions against offenders were recommended. Notification was received from federal courts of the termination of nineteen criminal prosecutions. Important seizures included candy containing alcohol. The law prohibiting the use of alcohol in candy has been in no way modified by the repeal of the prohibition law, the administration pointed out. Approximately 83,000 pounds of adulterated butter was seized. Among drug seizures of the month were bottles of Sirop d'Amis Gauvin Compound, consigned by J. A. E. Gauvin, Lowell, Mass. This "compound," which was recommended for coughs, colds, bronchitis and other ailments, was found to contain morphine. Among the criminal actions terminated were a fine of \$250 imposed on the Nestor Drug and Chemical Company, Chicago, and Julius Loeser for gross misbranding of a product which was called a cure for various maladies, a fine of \$200 on the Giles Remedy Company and Sanford F. Giles for shipping in interstate commerce an adulterated and misbranded germicide and one of \$200 on the French Sardine Company, Terminal Island, Calif., which had shipped cases of partially decomposed tuna fish.

Statement About Medicinal Whisky

The Federal Food and Drug Administration issued a statement, February 16, calling attention to the requirements of the Food and Drug Act concerning medicinal whisky as differentiated from a product intended exclusively for beverage use. Under the law, drugs listed in the U. S. Pharmacopoeia must conform to the definition in that authority and in the case of whisky the definition is more rigid than that for "straight whisky," recently issued by the Federal Alcohol Control Administration. Pharmacopoeia whisky must be aged at least four years in charred wood containers and its alcoholic content must be not less than 47 per cent and not more than 53 per cent by volume of absolute alcohol. A product varying from these specifications may be sold, if the label carries a statement of the strength, quality and purity but it must be marked "Whisky not U. S. P." Diluted alcohol with or without artificial flavor and color cannot be sold under the name "whisky," no matter how that name may be modified or qualified. Such a compound may be sold as a drug under a name other than whisky, if the name is not false or misleading in any particular. The announcement is not to be construed as modifying or changing the regulations of the Federal Alcohol Control Administration relative to the labeling of distilled spirits but shall be considered as an addition thereto, it was emphasized.

Complete Medical Socialism

The important fact that what is called national health insurance is so subsidized by the government and the employer that it is largely socialistic is generally overlooked in discussions, as well as the still more important fact that the evils of the system are due to this socialistic element. The principle of health insurance—that those who would be unable to pay the cost of medical attendance in the ordinary manner should provide for it by insurance—is of course sound and beyond criticism. The evils of the socialistic element as disclosed in the working of the system, have frequently been described in these letters. An important question, therefore, for any country in which the introduction of national health insurance is contemplated is "How far will the scheme be socialistic?" Another question is "Supposing it is decided that a moderate subsidy from the state is necessary, as in other countries, what is the danger of the state, under political pressure, being compelled to subsidize more and more and make the scheme more socialistic?" In England, constant demands are being made on the state for more and more, and the expenditure is much greater than was originally proposed. Moreover there is the danger that under political pressure complete socialization of the medical profession may be brought about. Under the socialist government this danger was so great that the British Medical Association brought forward a scheme of almost complete socialization, not because it or the profession wanted it but as a lesser evil than what might have been imposed by the government. With the crushing defeat of that government this scheme has disappeared. But the socialist party remains active and no one would be bold enough to say that it may not be in power some day. What may be expected from it is shown by the report in the *Tan* of an address of Mr. Somerville Hastings, a laryngologist, who is a prominent member of the Socialist Medical Association, to the Lewisham Division of the British Medical Association.

Medical services he said should be free to every one, payment for them being made out of the taxes on a whole time salary basis. Money was always a difficulty with patients, if the physician visits frequently, he is thought to be running up a bill, if he tries to avoid such a charge by staying away, he is reproached with neglect. The taxpayer admitted to a hospital would if able, pay the full cost of maintenance there but the medical charges would be covered by the taxes. Mr. Hastings referred to the services which in recent years have been removed from the province of the general practitioner and provided by the community—preventive medicine, infectious diseases, lunacy treatment of school children, much maternity work, tuberculosis, venereal diseases. Rheumatism, orthopedics and cancer might soon be added. At present the London County Council had no outpatient departments attached to its hospitals, but they were coming. There was too much time wasted by physicians in going round to see patients. Ill health cost the nation about \$1,000,000,000. The preventive medical service cost \$100,000,000 and the treatment services another \$450,000,000. He doubted whether the state was getting value for its expenditure. Under his scheme there would be unit services for 50,000 people and most of the work would be done in a central clinic by a staff of twenty physicians working in conjunction with specialists. Hospitals and convalescent homes would be attached to the clinics. Private practice would still be allowed to physicians who did not come into the service,

but the aim would be to make this so attractive that rich and poor would flock to it

Mr Hastings assumes the continuance of the resources now provided by a society that still retains, in spite of socialistic adulteration, much of the efficiency of individualism. The complete socialization of the medical profession is not likely to be brought about without the complete socialization of everything else. If this ever should be achieved in this highly industrialized country the results, it is said on good authority, would be much more disastrous than have followed the destruction of the capitalist system in the comparatively backward Russia. Mr Hastings might ask himself the question: With what efficiency does the Russian government supply the medical needs of the masses, or the much more important needs of food, clothing and housing? The fatal flaw in all socialistic schemes is that they take no account of the loss of efficiency due to removal of the incentive of individual advantage.

The Removal of Tonsils

Whether the frequent removal of tonsils now practiced as justifiable is much disputed. The Ministry of Health a short time ago issued a report showing that the operation was too frequently performed. The Fellowship of Medicine arranged a debate on the motion "That operations for the removal of tonsils are too often performed without adequate cause." It was proposed by the laryngologist Mr Herbert Tilley, who said that, for many of the subacute and chronic ailments of children up to the age of puberty and even adolescence, no treatment was so quickly restorative to normal and prolonged good health as removal of enlarged and diseased tonsils. But unfortunately this led to the belief that a disproportionate number of such maladies in children and only less frequently in adults, are due to "septic tonsils," which are often removed without adequate examination of patients for other possible causes of their symptoms. It has been shown that the lymphoid nodules of the tonsils provide a constant supply of lymphocytes and phagocytes, which destroy noxious organisms that reach the tonsils through the mouth and nose. Probably in this "warfare" some general immunization is produced. Mr Tilley said that it is not an uncommon experience to find in young patients who a year or so previously had their tonsils and adenoids removed that in the interval large patches of lymphoid tissue had been deposited on the posterior and lateral walls of the pharynx. Or the lower halves of the tonsillar fossae may become occupied by an upward growth of the adjacent lingual tonsils. This suggests an attempt of nature to compensate for the loss of the tonsils. Unfortunately the new deposits often lead to complaints of dryness and soreness of the throat and frequently an irritating cough—symptoms sometimes difficult to cure without cauterization.

Discussing What is a septic tonsil? Mr Tilley said that in children bacterial flora can always be detected in the tonsillar crypts and from normal adults yellowish white plugs of debris can easily be expressed from one or more recesses in the tonsil, and the bacteriologist would report the presence of broken-down epithelial cells, lymphocytes, leukocytes, fibrinous material and probably pathogenic microbes. Such plugs are not an adequate cause for removal of tonsils. The "chronic septic tonsil" which may be a menace to the individual, he held to be one in which the natural protective barriers have broken down and pathogenic microbes, with their toxins have entered the lymphatics of the tonsils and general circulation. The result is various degrees of inflammation of the tonsils with a history of recurrent attacks of acute tonsillitis and symptoms of mild general toxemia often associated with local manifestations, such as myositis, neuritis, arthritis and symptoms suggesting cardiac infection. Clinically the most concise answer to the question is Hajek's dictum: "The most certain proof

of a chronic tonsillitis is always the occurrence of repeated acute attacks." But, if such attacks are few and far between, the tonsils may equally be condemned on the following grounds: 1 The escape of pus from the crypts when pressure is applied to the tonsil. 2 An enlarged tonsillar gland behind the angle of the jaw, varying in size and sometimes tender. The neighboring anterior cervical glands may be in a similar condition. 3 A purplish red tinge limited to the anterior faucial pillar. This generally indicates streptococcal infection of the underlying tonsil and is frequently associated with arthritis. 4 Abnormal preponderance of leukocytes in material from the tonsillar crypts, frequently accompanied by general hyperemia of the pharyngeal and palatal mucosa. The size of the tonsil is no criterion of the degree of sepsis within it. A large tonsil may be far more harmless than another, which is small, retracted and fibrous. Once chronic infection has been established the tonsil should be removed. In cases of chronic neuritis, arthritis, disordered heart action, iritis and rebellious skin diseases, striking successes have been achieved. But unfortunately there are also failures in what appear to be identical conditions, which points to the conclusion that the cause of the symptoms was not discovered.

Mr Tilley drew attention finally to certain local and general factors, which he has found, cause enlargement or inflammation of the tonsils. If such conditions were more freely recognized and treated, many tonsillectomies would be unnecessary. They are as follows: 1 Deficiency diseases, such as rickets are commonly associated with enlarged tonsils. The same holds for deficiency of vitamin A, which frequently occurs in children brought up on excess of carbohydrates. 2 There is no need to remove slightly enlarged tonsils when the symptoms are typical of adenoid obstruction. Removal of the adenoids will frequently be followed by return of the tonsils to normal. 3 Dental sepsis is a frequent source of tonsillar congestion in children and sometimes in adults. 4 Many enlarged tonsils are due to infection of the nasal sinuses, particularly the antrum. This condition is far more common in children than is yet appreciated by laryngologists. It explains the large proportion of cases in which nasal discharge, cough and mild pyrexia continue after removal of tonsils and adenoids. 5 Nasopharyngeal symptoms, which include fulness of the tonsils, frequently accompany the advent of puberty. Removal of such tonsils would be reprehensible.

In seconding the motion, Dr J. Alison Glover, medical officer of the Ministry of Health, gave statistics to show that tonsillectomy is excessively performed. More than half the most carefully nurtured children in this country are now subjected to it whereas forty years ago none of their parents underwent it. While the incidence of tonsillitis is at least as high among the poor as among the rich, the children of the latter are operated on four times as often.

Measurement of Doses of X-Rays and Radium

Advances are being made at the National Physical Laboratory, Teddington, in methods of measuring doses of x-rays and radium. The work is under the charge of Dr G. W. C. Kave, superintendent of the physical department. Discussions between Teddington and the national laboratories of the United States and Germany are expected to lead to an international system of measurement at the congress to be held at Zurich next summer. Already measurement of the roentgen, the new x-ray unit, at the three laboratories, agree to within 0.5 per cent. The method depends on the power of the x-rays to make air a good conductor of electricity. The central part of the beam of x-rays is passed through a lead-screened chamber, and the rate at which electricity "leaks" from one side of the chamber to the other is measured. This method was worked out at Teddington and was used to standardize a less satisfactory

standard—the rate at which yellowish green pastilles are turned brown under the influence of radium. The full exploration of a beam of x-rays or radium will be possible by means of an instrument that need be no larger than a thumbnail but must first be compared with the standard recorder.

PARIS

Jan 10, 1934

Revision of the Premedical Course

Considerable stir was caused in the medical press by the recent announcement of the revised program of the premedical course, which must be completed by all candidates for admission to a French *faculté de médecine*. Heretofore these studies have been pursued in the *facultés des sciences* and comprised courses in physics, chemistry and natural history. It has frequently been alleged that these courses present too much theoretical knowledge that the physician has no use for in the practice of his profession. The *facultés des sciences* it is true, gave these courses a character that was not exclusively medical, since they prepared the way for scientific careers other than that of medicine. Complaints of physicians have become increasingly loud in recent years. The physicians finally succeeded in inducing the superior council of public instruction to revise these courses. The new certificate, or diploma, will cover "physical, chemical and biologic sciences." The new courses reduced the time spent on zoology and botany since the elements of these subjects that are useful to medicine are taught in the *facultés de médecine*. But it created general surprise when it was announced that the superior council (the majority of the members of which, by the way, are professors of pure science) had added, to make up for the trimming of the courses in zoology and botany, a complete program of higher mathematics, including trigonometry, logarithms, the calculation of curves, and exponential functions, which are of much less practical value for the mental training of the physician and are of a nature to discourage many prospective candidates. The medical profession has filed vigorous protests with the minister of public instruction and has demanded as preferable a return to the old system in vogue thirty years ago, when this preliminary instruction was given in the *facultés de médecine*.

A New Type of Sanitary Train

The Chemin-de-fer du Nord (Northern Railway Company) has put into service a special sanitary train to be used on its lines to facilitate radiologic examination of those of its agents who are employed in small localities, distant from hospital centers. Mr. Hirschberg has prepared a detailed description of the equipment of this modern train and has transmitted it, with the compliments of the company, to the Academy of Medicine. The train is composed of three special cars, one to serve for consultations and for roentgenologic examinations, a second car for the accommodation of the physician and the corps of assistants, and a third car that serves as a waiting room. This sanitary train, which functions with great success, has as its chief objective the application of prophylactic measures against tuberculosis, but it serves, at the same time as an evacuation center and directs to suitable institutions all patients, tuberculous or otherwise, who seek a consultation. Mr. Calmette, shortly before his death, emphasized the great importance of this ambulant dispensary as an aid in combating tuberculosis. Sanitary trains of this, or similar, type might be used also for the preliminary examination of the wounded in time of war. Soon after this sanitary train was put into service, a train of a similar type but even more luxuriously equipped was constructed by the government-controlled railways. It is designed to travel over all the lines of the govern-

ment railways and to visit more particularly the remote small localities in which medical organization is inadequate, to assist in giving clinical and roentgenologic examinations to the employees of the company.

A New Type of Municipal Hospital

The municipal council of Paris, wishing to take some adequate action in response to the protests launched by the physicians who complain that too many well-to-do patients are admitted to the hospitals of the *Assistance publique*, at reduced rates (although these institutions were established primarily for the indigent), without any additional remuneration of the heads of departments, who receive a fixed annual compensation from the *Assistance publique*, has decided to erect a large municipal hospital in the thirteenth *arrondissement* (ward), which will be in fact, a clinic exploited by the city administration. The patients will occupy separate rooms and will be attended by the physician of their choice, whom they will pay directly for his services, while the city will collect the hospital charges exclusive of medical attendance. There will be no chief physician. All physicians were to be permitted to attend their clients in this institution, but, at the request of a member of the city council it has been decided that only French physicians will be accepted, foreign physicians being excluded. No sooner was this plan announced than the private sanatoriums began to file protests, alleging that they would thus be deprived of the larger portion of their clientele, whereas they are under heavy expense and pay large income taxes, from which the municipal institution would doubtless be exempted. It is true, however, that these sanatoriums have very high tariff schedules, which is the chief reason why even well to do patients, during these times of stress, prefer to seek medical treatment in the hospitals which are delighted to receive them, as their income is augmented by these promptly paying patients.

Interpretation of the Sterilization Law

The law for the prevention of offspring with serious pathologic hereditary tendencies (THE JOURNAL Sept 9, 1933, p. 866) went into effect January 1. The diseases involved are of course precisely enumerated in the law. According to the law sterilization presupposes that the disease has been unequivocally diagnosed by a licensed physician even though, owing to attempts at concealment, it may have become only temporarily apparent. A plea for sterilization shall not be entered if the subject with hereditary taints, by reason of advanced age or otherwise, is incapable of reproduction, or if the health officer having jurisdiction has certified that the intervention would constitute a peril for the life of the person or if, being in need of institutional care, he is retained permanently in an institution. The sterilization shall not be performed before completion of the tenth year of life. Sterilization is effected, without removal of the testes or ovaries, by making the spermatic cords or the fallopian tubes impermeable or severing them. The operation is to be done in federal or communal hospitals or sanatoriums or in other institutions only in case they are willing to accept such patients. An absolute guaranty must be given that the intervention will be performed by a physician who has had surgical training. If a licensed physician through his practice, becomes acquainted with a person who is affected with a hereditary disease or grave alcoholism, he must notify, without delay, the health officer having jurisdiction. The same obligation rests on other persons who are concerned with the examination, therapeutic management or counseling of patients. If the official physician regards sterili-

zation as advisable, he shall endeavor to induce the patient in question, or his legal representative, to file a petition to that effect. If this is not done, he must file a petition himself.

For this purpose a questionnaire has been drawn up that applies particularly to persons with hereditary blood taints. For weakminded persons a questionnaire comprising an intelligence test has been prepared. If the court approves the sterilization, the official physician shall inform in writing the subject to be sterilized and shall demand that he (or she) submit to the intervention within two weeks. The notice should contain the names of the institutions to which application may be made. If the subject to be operated on does not file a petition of his own accord, he should be informed that the intervention will be undertaken against his will. The court shall countermand the order for sterilization if testimony given by the official physician having jurisdiction is to the effect that sterilization would imperil the life of the subject. If the person to be sterilized secures, at his expense, admission to a "closed" institution that will furnish a guaranty that reproduction will not occur, the court will, at his request, order that the intervention be held in abeyance as long as the person remains in the designated institution. This provision, which leaves open a way in which sterilization can be avoided (although at the expense of the subject's personal freedom), creates a distinction between rich and poor, to which the daily press has called attention in the hope that some way may be devised of furnishing the necessary financial aid to persons of limited means. After expiration of the delay set, the intervention shall be carried out with the aid of the police and the application of direct force, if necessary. In the case of juveniles, the intervention may not be carried out with application of direct force before completion of the fourteenth year. Neglect of the duty of notification renders a person subject to punishment.

For the execution of the sterilization law, eugenics courts (and superior courts) have been established throughout the reich. Attention is given first to patients who are already under medical supervision—that is, who are in institutions or who are receiving protracted treatment. It will then be the duty of the specially appointed eugenics boards to ferret out the remaining persons with serious hereditary and transmissible defects. According to estimates, the number of persons with hereditary disorders who are to be sterilized within a short time amounts to about 400,000. The sterilization law lists nine diseases as hereditary, with numbers somewhat as follows: congenital weakmindedness, 200,000; schizophrenia, 80,000; manic-depressive insanity, 20,000; epilepsy, 60,000; chorea minor, 600; hereditary blindness, 4,000; hereditary deafness, 16,000; grave bodily malformation, 20,000; hereditary alcoholism, 10,000; a total of 410,600. This number is composed about equally of men and women. It is evident that not all the persons concerned can be subjected to the sterilizing operation within a few weeks. The plan is to treat the more urgent cases first.

An estimate of the total expense must consider that the comparatively simple operation on a man costs about 20 marks (\$7.60). The total expenditure for the sterilization of 200,000 men would thus amount to about 4,000,000 marks (\$1,520,000). The intervention as applied to women is more complicated, and the charges may be estimated at 50 marks (\$19). The total expense involved in the sterilization of 200,000 women would accordingly range around 10,000,000 marks (\$3,800,000). Over against this expenditure of 14,000,000 marks (\$5,320,000), for the first few years, may be placed the economies effected by the prevention of offspring with serious hereditary taints. According to a recent estimate every patient with a hereditary disorder entails an average annual expense to the commune that provides for his care in an institution of 1,482 marks (\$563). On the basis of a low estimate the communes of the whole reich would expend more than 170,000,000 marks

(\$64,600,000) for the mental patients alone. In addition, a large part of the offspring with hereditary disorders must be educated in special schools, the annual expenditures for which throughout the reich amount to 40,000,000 marks (\$15,200,000). Berlin, for example, pays for the 8,000 pupils in its special schools 2,500,000 marks (\$950,000) more than for the same number of pupils in the *volksschulen*. The direct expenditures for patients with hereditary disorders, as reported by the reich, the lander and the communes, amount to at least the annual sum of 350,000,000 marks (\$133,000,000). Director Burgdorfer, of the federal bureau of statistics, includes in the financial burdens entailed by patients with hereditary disorders also the sums expended by the welfare agencies, the churches and private parties, and this places the annual disbursement that the public has to meet for the support of patients with hereditary disorders, and of asocial and criminal elements, at approximately 1,000,000,000 marks or \$380,000,000.

It is estimated that, after several decades, hundreds of millions of marks will be saved each year as a result of the reduction in the expenditures for patients with hereditary diseases. The funds for the care of such patients are furnished chiefly by the social insurance system, that is, by the *krankenassen*. Uninsured persons are taken care of generally by welfare aid societies. A written report must be made to the health authorities within three days after the intervention.

THE CASTRATION OF CRIMINALS

The law pertaining to the castration of criminals likewise went into effect, January 1. Some of the provisions have a medical interest. As measures of safety and moral regeneration, any of the following decisions may be reached: internment in a sanatorium, a drunk cure institution or an institution for withdrawal treatment, sterilization of dangerous perpetrators of crimes against good morals. Hardened criminals who are hopeless recidivists may be kept in custody for an indefinite period or for the duration of their lives. Dangerous criminals who commit sex crimes can be sterilized after age 21 if they have been previously sentenced for a corresponding crime and a prison sentence of at least six months was imposed. Consideration of all the facts in the case must show that the subject is a dangerous violator of moral laws as pertaining to sex. Evidence of a sentence imposed in a foreign country will be accepted as having the same value as a sentence imposed in Germany.

Any person who, through intoxicants, including narcotics, allows himself to get into such an intoxicated state as to be no longer accountable for his acts, and while in such a condition commits a punishable offense, may be given a prison sentence up to two years. Any person who procures without permission, for an inmate of an institution for withdrawal treatment, alcohol in any form, or other intoxicants, may be given a prison sentence up to three months.

Congress of Internal Medicine

This year's session of the *Deutsche Gesellschaft für Innere Medizin* will be held in Wiesbaden, April 9-12. The main topics on the program are: (1) "The Present-Day Theory of Hereditary Transmission in Its Application to Man," chief speaker, Eugen Fischer, Berlin; (2) "General Pathology of Hereditary Transmission," chief speaker, Freiherr von Verschuer, Berlin; (3) "Special Pathology of Hereditary Transmission of Internal and Nervous Diseases," chief speaker, Otto Naegeli, Zurich; (4) "Significance and Scope of the Localization Principle in the Nervous System," chief speaker, Otfried Foerster, Breslau; (5) "Physiology and Chemistry of the Sex Hormones," chief speaker, Adolf Butenandt, Danzig; (6) "Normal and Pathologic Functioning of the Ovaries," chief speaker, Robert Schroeder, Kiel. The chairman is Schittenhelm of Kiel, who directed also the previous congress, in place of Lichtwitz.

VIENNA

(From Our Regular Correspondent)

Dec 12, 1933

The Tannic Acid Treatment of Burns

Since the tannic acid treatment of burns became known here, a large number of physicians, particularly in the "accident hospitals," have adopted this method. In order to bring the method to the attention of more physicians a number of lectures and demonstrations on the subject were held at a recent session of the Vienna Medical Society. It was stressed that the chief advantage of this method holds not so much for adults as for the burns of children, whose lives are thereby saved for ordinarily the prognosis in the case of children with burns is much more unfavorable than with adults. The new method reduces the pain and dispenses with bandages and the use of the protracted water bath. In combination with blood transfusion and injections of sodium thiosulphate, the results have been excellent. Of all the methods recommended for the use of tannic acid, the following has proved to be the most effective: Moistening or spraying of the burned portions of the body every quarter of an hour, with a 2.5 per cent solution over a period of from twelve to eighteen hours. As soon as the crust has formed, the patient needs little further care. The crude tannic acid is superior to the purified, and the best effects are secured if the solution is applied at a temperature of 30° C (86° F). The stay in the hospital is reduced at least 20 per cent. Scar formation and contractures are much more rare and more pliable than formerly. The sooner the tannic acid is applied, the better the results. The mortality has been reduced from 13.5 per cent to 2.4 per cent whereas with the trinitrophenol therapy formerly employed the mortality ranged from 11 to 40 per cent.

Roentgenologic Treatment of Metastatic Cancer of Lung

Dr. Borak demonstrated before the Gesellschaft der Aerzte several cases of metastatic tumors of the lung which are now regarded as virtually healed. A woman aged 61 who, seven years previously, had a solid cancer of the right mamma had a radical operation, which was followed by irradiation. The operative area is thus far free from recurrences. In 1930, however, a metastasis developed in the region of the left hilus glands, compressed the bronchus and esophagus and pressed on the pneumogastric nerve which condition was associated with upper displacement of the diaphragm and atelectasis of the lung. The symptoms were cough, fever, blood-stained sputum and loss of weight. The patient received in September, October and December 1930 roentgen irradiations equivalent to 2,400 roentgens for each series, distributed over the breast and back. The pressure symptoms disappeared gradually, and today there is visible in the hilus only a strip of shadow at the former site of the tumor. The subjective condition of the patient is excellent, while normal body weight and full working capacity have been restored. This result has persisted for three years. Dr. Borak exhibited roentgenograms of several other cases: one case with a solitary metastasis dating back to the year 1929, and other cases with multiple foci in both lungs going back to 1930. These cases were metastases following cancer of the breast and belonged to the type of a solid cancer. The observations of other roentgenologists go to show that this type in contrast with adenocarcinoma, reacts well to roentgen rays. Much heavier doses must, however, be employed than was formerly the custom and is still the custom, to a certain extent.

Albin Haberdar

Prof. Albin Haberdar, the distinguished medicolegalist, died, recently, after a long illness at the age of 66. Haberdar was a pupil of Eduard Hofmann. While a student he was appointed

an assistant in the institute, an excellent proof of his unusual ability. He was then assigned to the Klinik für Chirurgie and later to the Klinik für Gynäkologie. After the death of Professor Kolisko, who, after Hofmann's demise, had become director of the Institute of Legal Medicine, Haberdar took over, as a young man, this important post, and established a school of legal medicine, which was attended by physicians and jurists from all parts of the world. His originality and wit were proverbial while his knowledge was profound. His classic Textbook of Legal Medicine, which he kept up to date, became a standard work, a mine of information for every person interested in legal medicine. The journal *Beiträge zur gerichtlichen Medizin* was founded and edited by Haberdar, and in it he published many extremely valuable articles from his own pen. Many of Professor Haberdar's pupils are serving today as forensic experts in Austria and in foreign countries. Particularly well known is his critical attitude toward the problem of artificial (criminal) abortion for which he rejected social and eugenic indications. During his last illness of two years' duration his pupil Professor Werkgartner took charge of his work and is likely to be appointed his successor. Haberdar's death is a severe loss for the faculty of the University of Vienna. He was one of the last of the "old guard" which before the war, had made Vienna the Mecca of European students.

JAPAN

(From Our Regular Correspondent)

Dec 30, 1933

The Increase in the Number of Physicians

The total number of physicians in Japan in 1932 amounted to 50,068 according to a report made by the home department, which shows an increase of 1,969 over the number of the previous year. Of these physicians the practitioners number 46,029 or 1,140 more than in 1931, the number in every 10,000 of population is 694. Those who work in cities number 23,736, those in towns 10,204, and those in villages 12,089.

The number of dentists is reported to be 17,164 in 1931 it was 15,988. The number of midwives was 54,655 (in 1931, 52,537). The number of names removed from the medical register for various reasons in 1931 was 1,014. In the last ten years, 968 practitioners each year have been removed from the register. In the present school year from last April to March 1934, the graduates of medical colleges, universities and other schools will amount to 3,115. The rapid increase of the population may more or less justify the increase of physicians, nevertheless this is the age of the flood of doctors. The present system of medical education here is a point of issue on every side, for this system when founded about sixty years ago was based on the German system, and there has been little change. Four years of medical studies are said to be too few for those who want to practice soon after graduation but to lengthen them the preparatory course must be shortened.

Three Professors Dismissed for Selling Degrees

The following disgraceful incident shows how hard it is for practitioners to succeed in these hard times. In this country the title of Doctor of Medicine is almost a prerequisite for a practitioner to have a large practice. This title is given when a thesis for the doctorate is approved by the college or university staff. Three professors of the Nagasaki Medical College which is under government management, were accused by the procurators of the Nagasaki local court of selling through bribery the scholastic degree of doctor of medicine. The eight practitioners who bought the degrees were also accused. This caused a sensation all over the country as the occurrence was the first of its kind in Japanese scholastic circles. All the students of that medical college although forbidden to assemble

in protest against the scandal, managed to voice a united refusal to undergo examination by the present teaching staff. On hearing the indignant demands of the students, the entire teaching staff decided to resign, including the president, sixteen professors and nine assistant professors. The three professors, one of whom is reported to be the most famous gynecologist in this country, were taken in custody, while the others are reported to have nothing to do with the scandal they tendered their resignations. The education office, however, rejected the joint resignation of the president, sixteen professors and nine assistant professors. The accused professors were dismissed from their posts.

The Society of University Professors of Japan expressed deep resentment, as the incident was not in keeping with the dignity of education.

The exposure of the scandal may be attributed to the friction among the professors, who are divided into two cliques, one group being made up of those who graduated from the Kyoto Medical University and the other the Tokyo University group. Cliques in medical schools here have long been the cause of trouble not only in this ancient college but in many other schools of medicine. Even the education office is at a loss to know what to do with this problem and so has left it unsolved.

The Rockefeller Public Health School in Japan

The Rockefeller Foundation in 1930 proposed the donation of a large sum of money to establish an institution to train medical workers and experts. The proposal, however, seemed to be abandoned in 1931 when the foundation announced the discontinuance of new enterprises. But recently it was decided to go ahead, as it was planned at first. In the cabinet council, December 21, the acceptance of the donation was recognized by the government. The new institution is expected to be completed in two years. According to the announcement by the sanitary bureau of the home office, the new institution will train and teach those who want to be public health workers, while medical graduates will be given postgraduate training. As there has not been such an institution in Japan, social medical problems have not been investigated. Those problems, heretofore untouched, will immediately be taken up. Attached to this institution in the local towns and villages will be the "health house," where those who graduate from the central institution will work for a while. The expense of maintenance will be contributed for three years by the foundation, and then the local houses will be put under the management of the local government.

The Practitioners and the Government

What most worries the practitioners in these hard times, says the *Medical Report*, is what will become of them if this condition endures. The government seems obliged to neglect the medical profession when questions of social policy arise. The government tries at every opportunity to require cheaper medical service for the middle and lower classes by encouraging the clinics and by the extension of health insurance. The national plan of health insurance, when completed, will include more than 20,000,000 people in the middle and lower classes. On the other hand, in the schools, tuberculosis prevention work is much discussed, as there are more than 250,000 tuberculous children in the primary schools. Physicians should immediately be attached to every school, the education office declares. The total number of the primary schools amounted to 25,626 in 1932, and if one physician is attached to two schools about 12,000 physicians would do school work exclusively. If the national health insurance succeeds it will come to pass that many will be government physicians and work on a salary. There is also a tendency to increase government work in disease preven-

tion. Almost all physicians will be in the employ of the government, and the character of medical practice, which has been individualistic for centuries, will undergo a change.

Asylums for Opium Addicts

Two large asylums for opium addicts have been built in the capital of Manchukuo, in which republic the number of addicts is estimated roughly at 1,800,000. Dr. Ito, vice president of the new asylum in the capital, says that the government is going to eradicate opium poisoning completely in half a century. The new asylum in Mukden will soon be enlarged to accommodate more than 2,000 cases a month. It will not only aim to cure the cases of poisoning but at the same time to cure addicts of the habit of using opium while kept there, some will be initiated into manual home work and their steady employment is expected to help them to break the habit. This asylum is therefore a hospital, on the one hand, and an employment office, on the other. Much hardship is expected to be encountered, for the habit of using opium in this country has been customary for a long time.

Postpone Adoption of Metric System

The establishment of the metric system as the legal system of weights and measures for Japan will be postponed for five years from next July under a decision of the ministry of commerce and industry. The sole reason for the postponement is that the people in general are not yet well enough acquainted with the system, although it was ten years ago that it was officially stated that the new system would be the legal system for this country. It is said that the new system will cost a great deal in changing the records of land ownership and taxation, and some architects say that without the old system great inconvenience will occur in their work. Japanese physicians have used the metric system for a long time.

BELGIUM

Dec 27, 1933

International Association of Preventive Pediatrics

The third conference of the International Association of Preventive Pediatrics, which constitutes a section of the Union internationale de secours aux enfants, was held in Luxemburg. Two topics were discussed at the session, the first being "Prophylaxis in Infantile Paralysis." Drs. Rohmer and Willemijn Cloc considered the factors that may serve as a basis for the establishment of prophylaxis. The nasopharyngeal mucosa and the salivary glands are both a port of entry and a route of elimination for the virus. In all probability, transmission does not occur through human contacts. This assumption is supported by numerous clinical and epidemiologic facts. Transmission by water (the Kling theory) is not impossible. The duration of the incubation appears to range between ten and fourteen days. Contagiousness does not usually exceed three weeks from the onset of the disease. The morbidity is low, as most persons become immunized or have already been immunized during a previous epidemic. Thus, 90 per cent of the urban population and 50 per cent of the rural inhabitants are found to be immunized. Eighty per cent of the cases observed in a region in which the infection is endemic concern children under 6 years of age who have had no opportunity to become immunized.

Dr. Wallgren distinguishes, among the prophylactic measures, those that aim to prevent infection (prophylaxis of exposure) and those designed to prevent persons exposed from coming down with the disease (prophylaxis of predisposition). The prophylaxis of exposure has two chief tasks: (1) to check the dissemination of the infectious agent and (2) to prevent its infec-

tive action on man Point 1 presupposes isolation of patients and neutralization of urine and fecal matter, the avoidance as far as possible of all contacts with strangers, and the closing of schools and playhouses Point 2 presupposes avoidance of contaminated drinking water and food, inspection of all food products, avoidance of contacts with patients, and observance of strict hygiene and scrupulous cleanliness Resistance to the disease depends on (1) certain specific factors of biologic immunity, and (2) certain specific constitutional and physiologic factors

The Brussels Center of Puericulture

The Duchess of Brabant, who was welcomed by Count Carton de Wiart, minister of health and social insurance, opened formally the Pediatric Clinic of the Center of Puericulture Constructed in accordance with modern ideas, the Pediatric Clinic has accommodations for 110 infants The rooms, separated by glass partitions, face a covered terrace and contain about everything that a child needs The basement has a special kitchen, which comprises three rooms In the first room the infants' drinking bottles are washed, whence they pass into the middle room, the kitchen proper, where they are filled and sterilized Thence they are taken to the refrigeration room, whence they are distributed to the various floors

The Center of Puericulture serves as a consultation center on infant care, to hospitalize sick premature and weakly infants, to supply a home for abandoned mothers and infants to train mothers in the care of children, and to create a training school for nurses The institute will be also a diagnostic center for children

Prevention of Specific Acute Disorders of Infants

In his discussion of the second main topic "Prophylaxis of Specific Acute Disorders of Infants," Dr Rott emphasized that prophylactic measures should be based on a clinical and sociological inquiry into conditions favorable to the development of the disease

Dr Frontali said that prophylaxis covers the following points (1) mechanical protection of the child against the source of infection isolation of the healthy child from infected persons, open individual cubicles in hospitals, which are recommended, (2) habituation to climatic conditions, life in the open air (3) a balanced diet, (4) vaccinoprophyllaxis, with which the speaker had secured encouraging results, (5) medicinal prophylaxis (a) general, (b) local nasal instillations of disinfectants

Marriages

WILBORN E UPCHURCH, Atlanta, Ga, to Miss Katherine Crowell Middlebrooks of Haddock, Nov 18, 1933

WILLIAM A RUNKLE, Memphis, Tenn, to Miss Louise Evelyn Duke of Grenada, Miss, January 8

MILNER CROCKER MADDREY, New York, to Miss Sara Jean Willis of Charlotte, N C, January 19

ROY C FRAVEL, Woodstock, Va to Miss Adelaide Rebecca Smith of Clifton Forge, Dec 24, 1933

CHARLES S VENABLE to Mrs Eleanor Herff Johnson, both of San Antonio, Texas, Dec 16, 1933

WILLIAM LLOYD EASTLACK to Miss Muriel E Reynolds both of South Boston, Va, recently

FRANK MERRILL WATTLES to Miss Charlotte Olivia Grimm, both of Palatka, Fla, January 11

EDWIN F CAVE, Boston, to Miss Louise Fessenden of Chestnut Hill, Mass, Dec 9, 1933

SIDNEY TERRELL PARKERSON, Unadilla, Ga, to Miss Mary Raby of Vienna, January 3

JAMES STEWART MILLS to Miss Margaret Gaines Grace, both of Cincinnati, January 6

Deaths

Robert Wilson Shufeldt ♂ Major, U S Army, retired, Washington, D C, Columbian University Medical Department, Washington, 1876, Civil War veteran, appointed assistant surgeon in 1876, retired as a captain for disability in line of duty in 1891, promoted major, retired in 1904, placed on active duty from 1918 to 1919, surgeon with Generals Merritt, Crook and Sheridan in frontier Indian wars 1876-1881, curator of the Army Medical Museum, in 1882, honorary curator at the Smithsonian Institute, under Baird, and in 1895, delegate to the British Association for the Advancement of Science from Royal Australasian Ornithologists Union in Melbourne in 1914, author of numerous articles on the study of ornithology, anthropology and geology, aged 83, died, January 21, of arteriosclerosis

J M Arthur Rousseau, Quebec, Que, Canada, Laval University Faculty of Medicine, Quebec, 1895 dean and professor of clinical medicine at his alma mater, in 1920 president of the Association of French Speaking Physicians of North America, past president of the Canadian Tuberculosis Association officer of the Legion d'honneur on the staff of the Hopital du Saint Sacrement, aged 62, died, January 14, of pneumonia

Oscar Amadeus Hansen ♂ Major, M C, U S Army, Fort Leavenworth, Kan, Bennett College of Eclectic Medicine and Surgery, Chicago 1906, University of Illinois College of Medicine, Chicago, 1907, served during the World War, entered the medical corps of the regular army in 1920 as a captain and in 1929 was made a major, aged 56, died, January 31, of arsenic poisoning

Espy Kerl Schurtz ♂ Waterloo, Ind Indiana Medical College, School of Medicine of Purdue University, Indianapolis, 1907, served during the World War, aged 54 on the staff of the U S Veterans Hospital Jefferson Barracks, Mo, where he died in January following an operation for strangulated hernia and diabetes mellitus

Zanvill David Klopfer, Chicago Jenner Medical College, Chicago 1908 College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1910, formerly coroner's physician on the staff of St Elizabeth's Hospital, aged 62, died, February 3, of cerebral hemorrhage

Henry Everett Monroe ♂ Shelbyville Ill, Medical College of Ohio Cincinnati, 1899, past president of the Shelby County Medical Society served during the World War, aged 58, on the staff of the Shelby County Memorial Hospital, where he died, January 30, of acute dilatation of the heart

George Coke Williams, Anniston, Ala (licensed by Calhoun County board of medical examiners of Alabama in 1881), member of the Medical Association of the State of Alabama, formerly member of the state legislature, aged 82, died, January 25, of hypertrophy of the prostate and uremia

Guy William Rubush, Indianapolis, Indiana University School of Medicine Indianapolis, 1913, member of the Indiana State Medical Association, aged 53, on the staffs of the Methodist Hospital, City Hospital and St Francis Hospital, where he died, January 13, of pneumonia

Abner Ormel Shaw, Portland, Maine, College of Physicians and Surgeons in the City of New York Medical Department of Columbia College, New York, 1863, member of the Maine Medical Association, Civil War veteran, aged 96, died, January 27, of pneumonia

Walter Oling Parrish, Rector Ark, University of Nashville (Tenn) Medical Department, 1898, member of the Arkansas Medical Society past president of the Clay County Medical Society, served during the World War, aged 58, died Dec 30, 1933

Arthur Albert Schmidt ♂ Postville Iowa, Keokuk Medical College, 1893, past president of the Allamakee County Medical Society, health officer of Postville aged 62 medical director of the Postville Hospital where he died, January 22, of septicemia

Frederick Goodman Sanford ♂ Jersey Shore Pa, Western Pennsylvania Medical College Pittsburgh 1901, medical director of a hospital bearing his name, aged 55, died January 28, in the Johns Hopkins Hospital, Baltimore, of amebic dysentery

Herbert P Byers, Melita, Manit, Canada, Manitoba Medical College Winnipeg 1890, for many years health officer of Melita and the municipality of Arthur, coroner and medical

officer to the Canadian Pacific Railway, aged 73, died, Nov 24, 1933

Isaac Charles Munson ♂ Avoca N Y University of Vermont College of Medicine, Burlington, 1897, health officer of the consolidated health district of Avoca Steuben County, aged 58, died, January 4, in the Bath (N Y) Hospital

Joseph Clarence Tappan, Derry, N H, Columbian University Medical Department, Washington, D C, 1899, member of the New Hampshire Medical Society, aged 62, died, Dec 19, 1933, of injuries received in an automobile accident

Grace Greenwood Tinney, Norton, Kan, Woman's Medical College, Kansas City 1902, member of the Kansas Medical Society, on the staff of the Laird Memorial Hospital, aged 55, died, Dec 19, 1933, of cerebral hemorrhage

Joseph Russell Taylor, Harrisburg Pa, University of Maryland School of Medicine and College of Physicians and Surgeons, Baltimore, 1919, served during the World War, aged 39, died, January 7, of heart disease

Alexander Waters Ransley, Spring Mill, Pa, University of Pennsylvania School of Medicine, Philadelphia, 1875, formerly on the staff of the Philadelphia General Hospital, aged 82, died, January 28, of pneumonia

Ferdinand N Hunt, Fairmont, Minn, Missouri Medical College, St Louis, 1884, an Affiliate Fellow of the American Medical Association, aged 77, died, February 1, of injuries received from a fall on an icy sidewalk

Claude Mattingly ♂ Austin, Texas, University of Texas School of Medicine, Galveston, 1926, served during the World War, aged 38 was found dead, February 1, of narcotic poisoning, presumably self administered

Jefferson D Wilcox, Willacoochee, Ga, Southern Medical College, Atlanta 1882, veteran of the Spanish-American War, formerly member of the state legislature, aged 77, died, Dec 21, 1933, of heart disease

Antoninus S Sorgi, Stamford, Conn, Royal University of Palermo Faculty of Medicine and Surgery, Palermo, Italy, 1892, aged 66, died, January 18, in the Stamford Hospital, of carcinoma of the sigmoid

Olin E Newton, Fayette, Ala, Birmingham Medical College, 1911, member of the Medical Association of the State of Alabama, aged 52, died, Dec 12, 1933, in the Walker County Hospital, Jasper

John Jellison Moffett ♂ Greenville, Ohio University of Colorado School of Medicine, Denver, 1912, on the staff of the Greenville Hospital, aged 47, died, January 17, of a self-inflicted bullet wound

Walter Smith Putnam, Millersburg Ohio Cleveland College of Physicians and Surgeons, Medical Department of the University of Wooster, 1887, aged 70, died, January 5, of cerebral hemorrhage

Sumter B Battey, New York University of Georgia Medical Department, Augusta, 1884, aged 72, died, February 2, of heart disease

Correspondence

VITAMIN H

To the Editor—In a previous communication (THE JOURNAL, Nov. 4, 1933, p. 1499), I inadvertently mentioned Kuhn's reference to a "vitamin H" as appearing in the *Berichte der deutschen chemischen Gesellschaft* 66 B, 1933, page 1934, instead of page 317 of the same volume, and erroneously interpreted H as having been considered an antipellagra factor. A more recent review by Gyorgy and associates (*Klin. Wchenschr.* 12:1241, 1933) clarifies somewhat the relation between the skin changes and the factors G and H. The authors do not agree that the early skin manifestations in G-avitaminosis in rats compare throughout with similar symptoms in human pellagra. But Goldberger and others observed in G-deficient animals, though inconstant, other forms of skin changes which resembled pellagra less than a simple seborrheoid-desquamative condition, in striking agreement with the intensive changes produced by the authors in rats by H deprivation, with B₆ available. Reference even to Gyorgy's initial report on H (*Ztschr. f. arztl. Fortbild.* 28:377 [June 15] 1931) reveals no information on the method of its preparation.

W. A. PEABODY, PH.D., Richmond, Va.

ULCERATIVE COLITIS

To the Editor—I am impelled to reply to the communication of Drs. J. A. Bagen and L. A. Bue in THE JOURNAL, January 6, under my article entitled "The Present Status of Idiopathic Ulcerative Colitis, with Especial Reference to Etiology," which appeared in THE JOURNAL, Nov. 25, 1933, page 1687, in order that their communication might not confound some of the issues discussed in my paper.

There is no basis for the inference that the brevity of my references to the material of Drs. Bagen and Bue do not give an accurate impression of what they have stated and done. The impressions and conclusions that I conveyed were my interpretations of the context of their published data. References to the original sources were given so that those interested and capable of critical analysis, particularly of bacteriologic-pathologic literature, might consult them.

The disparity in our views, in consequence of their communication, appears to be more apparent than real, for now they state that they have modified their ideas and recognize "that gaps might exist" in their concepts of the etiology of chronic ulcerative colitis. These observations, coming from the original proponents of a specific etiology on which specific therapy had been based, are to me tantamount to saying that at this time there is no proved specific etiologic factor and consequently there is no specific therapy. This, in its essentials, is confirmatory of my view based on experimental and clinical observations first expressed in 1927, a view discussed in some detail more recently in the paper to which I have referred.

If it is destructive and a disservice to the sick to state, as a result of research and clinical experience that as yet there is no specific etiologic factor and no specific therapy in chronic ulcerative colitis and that in consequence the ultimate response to treatment in many with severe manifestations of this condition is unsatisfactory, how should one characterize the efforts of those who, for years, have emphasized specificity of etiology and of therapy, and who, although no longer stressing a definite causative micro-organism and specific therapy, fail to speak out in their articles as forcefully and as unmistakably of their changed point of view? The fact remains that the sanguine note struck by these writers in the present nonspecific therapy of ulcerative colitis by methods available to every practitioner

unfortunately is not reflected in the literature as the experience of my other large medical center adequately observing, over years, a relatively large number of severe cases of this disorder.

MOSES PAULSON, M.D.,
The Johns Hopkins Hospital,
Baltimore

ANONYMOUS COMMUNICATIONS and queries on postal cards will not be noticed. Every letter must contain the writer's name and address but these will be omitted, on request.

SKIN TEST FOR TUBERCULOSIS

To the Editor—Is the tuberculosis skin test positive for persons once tuberculous, who have now recovered? If so what are the benefits to be derived from testing a group of school children? Please omit name.

M. D. Oklahoma

ANSWER—The intradermal tuberculin test (Mantoux) usually remains positive after the disease has been brought well under control. How long the test remains positive can be determined only by periodic tuberculin tests of the same group of individuals over long periods of time. Unfortunately, this has not been done in large numbers, so that figures are not available. The development of the primary focus of tuberculosis usually results in a positive tuberculin reaction. Evidence has accrued to show that some children with a positive reaction later do become negative. In such cases it is assumed that the foci of bacilli have been completely destroyed or so walled off that their products have no means of communication with the body tissues. No one knows just what percentage will bring their primary lesions so completely under control as to attain such a result.

As there is no control over reinfection of a child with tubercle bacilli from exogenous sources, one must always consider the possibility of the allergy indicated by the tuberculin test being kept up through reinfection. If it is granted that the majority of children who develop primary tuberculosis remain positive reactors to the tuberculin test throughout their lifetime, there are nevertheless great benefits to be derived from testing a group of school children. The older literature abounds with statements to the effect that nearly all children of school age have been contaminated with tubercle bacilli and therefore have primary tuberculosis. However, owing to reduced opportunities for infection, large numbers of children today are growing into or have reached adult life without contamination with tubercle bacilli. In fact in many parts of the United States, 70 per cent or more of the young adults have not been contaminated with tubercle bacilli.

The lower the incidence of positive tuberculin reactors in any group of persons including school children, the more valuable the tuberculin test becomes. In many groups of school children tested during the past five years, 10 per cent or less reacted positively to the test. Each child who does react positively has been exposed. This is an important fact, since through examination of his associates one may find the source of exposure in the body of a person having unsuspected tuberculosis. Moreover, each child reacting positively has a focus of tubercle bacilli somewhere in his body. Therefore, further examination is indicated in an attempt to locate the focus and to study its extent. If the focus is not found by the physical or the roentgen examination it is only because these methods are too crude, therefore, such children should be examined periodically, in order to bring to light any focus that later becomes large enough to be detected. One is then in a position to treat these children before their lesions have broken down, markedly reducing the chances of recovery, and before they have disseminated their tubercle bacilli to others.

INJECTIONS INTO HEART FOR RESUSCITATION

To the Editor—I read in THE JOURNAL some time ago that no one would be justified in injecting epinephrine into the heart in case of apparent death. Would you still say that? If you think it might be justified, will you tell me the size needle to use and the point of insertion? It seems to me to be important enough to justify the query.

NATHANIEL F. CREEVER, M.D. Greenfield, N. H.

ANSWER—Intracardial injection therapy for the resuscitation of the stopped heart in cases of apparent death is a simple procedure worthy of trial in many instances of unexpected cardiac collapse. Many substances in addition to epinephrine have been used successfully in restoring cardiac activity,

Hyman has described twelve such drugs (Resuscitation of the Stopped Heart by Intracardiac Therapy, *Arch Int Med* 46:553 [Oct] 1930). In this article it is stated that the preferred needle for intracardiac injection should be at least $4\frac{1}{2}$ inches (11.4 cm) long for use in an adult and $2\frac{3}{4}$ inches (7.3 cm) long for a child. The needle should be constructed of 19 gage unbreakable stainless steel.

The site of insertion has been the subject of considerable investigation by many workers in this field, as the restoration of automatic cardiac activity is said to be due more to the trauma produced by the prick of the needle in the myocardium rather than to the specific pharmacodynamic action of the drug injected, the site of the injection becomes a matter of especial importance. The first contraction of the heart muscle after the injection is always an extrasystole arising from the ectopic focus developed by the action current of injury as the result of the needle prick.

According to Hyman (*THE JOURNAL*, May 20, 1933, p 1628), when the injection is made into the ventricle a series of ventricular extrasystoles may develop, if there has been a prolonged cardiac arrest with a high degree of myocardial anoxemia there may arise a paroxysmal ventricular extrasystolic tachycardia which is quickly converted into ventricular fibrillation and fatal cardiac collapse. If, on the other hand, the injection is made into the right auricular area the same physiologic phenomena may develop with the production of a paroxysmal auricular extrasystolic tachycardia and subsequently auricular fibrillation. The difference here is that, whereas ventricular fibrillation is incompatible with the maintenance of life, auricular fibrillation is a well known and easily handled clinical entity. The site for intracardiac injection, therefore, regardless of the substance used, should be into the right auricle.

It is interesting in this connection to note that the artificial pacemaker developed by Hyman at the Witkin Foundation for the Study and Prevention of Heart Disease, New York, utilizes a small electric current to control the ectopic rhythm in the right auricle instead of permitting the action current of injury to dominate the rhythm of the heart in a hit or miss method. The right auricle of the heart is easily approached by inserting the needle into the third or fourth interspaces about 1 cm to the right of the sternal margin.

DISPAREUNIA IN DOUBLE VAGINA AND UTERUS

To the Editor—I have a patient aged 21 years who recently came to me complaining of painful intercourse. She has been married fourteen months and it was impossible for her to have intercourse for two weeks following her marriage owing to severe pain and tightness of the vaginal canal. Bimanual and speculum examination revealed two separate vaginal canals and two cervixes but I am not able to differentiate whether this condition is a uterus duplex (didelphic) or uterus septus. In either event what is the safest procedure in removing the septum to relieve the painful intercourse and would it be advisable for the woman to become pregnant? If pregnancy occurred in the two horns at the same time would the danger encountered warrant a cesarean section at term or would sterilization at this time be a safer procedure? How frequently does this anomaly occur?

M D Oklahoma

ANSWER—A double vagina does not often cause dyspareunia. In fact, many women who have this anomaly are not aware of it, even after having been married a long time, until a physician tells them about it. Not infrequently even a physician will fail to detect the septum in the vagina and not until dystocia arises in labor will his attention be directed to it. The reason for easily overlooking a double vagina is that in most instances in which this abnormality is present only one vagina is used for coitus. Because of this the other vagina remains small and it may even have a hymen which remains unruptured. In spite of this menstrual blood can and does escape through the smaller vagina but the women who have such anomalies do not know from which vagina the menstrual blood escapes. Hence a double vagina rarely produces disturbances in the sexual life of a woman until labor sets in and even then dystocia is uncommon from this source. It may be possible in the case cited to stretch one vagina forcibly under gas anesthesia and at subsequent visits dilate this vagina with glass dilators. If however the septum appears to be tense it may readily be removed by placing one long clamp on the upper edge and another on the lower edge and removing the septum that lies between the two clamps. The portions that remain in the teeth of the clamps should then be sutured by means of an over and over continuous suture. Frequently there is a free space between the cephalic end of the vaginal septum and the vault of the vagina so that a finger can be inserted from one vagina into the other at this point. In this case no sutures are necessary at the vault of the vagina. If however the septum

is continuous with the dome of the vagina, sutures will also have to be placed here between the two cervixes. A small gauze pack saturated with petrolatum should be placed in the vagina for twenty-four hours to prevent undesirable adhesions. In some instances, removal of a vaginal septum has cured sterility.

A uterus duplex is not a contraindication to pregnancy. In fact, most women with this abnormality are prolific and, while many have disturbed labors, this is not true of the majority of them. Furthermore, even in spite of childbirth, some cases are so entirely devoid of complications that the abnormal condition of the uterus is not recognized.

Abortions are more common in cases of double uterus than in cases of normal uteri. In some series of cases, abortion occurred in more than 25 per cent of the pregnancies. An ovum may develop in one or the other uterus or in the two uteri at the same time. Usually the nonpregnant uterus is pulled back of the pregnant one and it may or may not produce dystocia. Labor is usually prolonged as a result of underdevelopment of the uterine musculature and especially of interference by the nonpregnant uterus. Complications may arise because of abnormalities in presentation, as breech presentations are common in cases of double uterus. However, since labor is terminated spontaneously in most instances of uterus didelphys, such cases should be managed in the same way as other cases. Intervention should be considered only when evidence of trouble arises. In most instances in which complications occur, a cesarean section should be done, but it is not necessary or advisable to sterilize these patients at the time of their first labor.

THIOCYANATE POISONING

To the Editor—Mrs H S aged 65 suffering from chronic incipient pulmonary tuberculosis and hypertension (about 220 systolic) called a physician and he prescribed for her sodium sulphocyanide in crystal form a teaspoonful three times daily in water after meals. She took the first dose in the evening and slept better than usual but says that she felt queer next morning but took the dose. This time she had a feeling that she was going to die and lapsed into unconsciousness and at noon her husband gave her the third dose but she was unaware of taking it. During the afternoon she began to have twitching and at 10 p m had a severe convulsion. Another physician was called and he told her to discontinue the medicine. She was taken to the hospital the next morning in an ambulance in clonic and tonic seizures throwing herself and rolling about. There was complete urinary retention. Catheterization resulted in the withdrawal of 660 cc of urine. Lumbar puncture was done and the fluid found normal to pressure and microscopy. A spinal Wassermann test was negative. Twenty five cubic centimeters of 10 per cent magnesium sulphate was given to control the convulsions. She received codeine 0.0327 Gm at four different intervals during the night. She showed considerable improvement on the third day but still had to be catheterized and was confused mentally. She was rational on the fourth day and voided urine voluntarily. The highest temperature was 100 F on the second hospital day with a pulse rate of 100. The patient left the hospital on the fifth day in a wheel chair but has been unable to use her lower extremities and after six months can walk with assistance. Merck suggests a dose of 0.1 Gm three times a day. Am I right in concluding that this is a case of poisoning by sodium sulphocyanide or sodium thiocyanate?

M D, Washington

ANSWER—The description of the symptoms and signs is entirely compatible with a diagnosis of thiocyanate poisoning. It is not surprising that such poisoning occurred with the huge doses administered, the teaspoonful of crystalline sodium thiocyanate was approximately equivalent to 4 Gm of the salt. The usual therapeutic dose does not exceed 1 Gm daily. Thus, twelve times the usual amount was administered in twenty-four hours. It is, however, surprising that the patient survived, particularly as this drug is but slowly eliminated and cumulative effects are common.

The tolerance to thiocyanate salts is not uniform, in some persons even small amounts are known to have produced serious intoxications. Renal functional impairment appears to delay the excretion of the drug, and cumulation and intoxication are more prone to develop when nephrosclerosis coexists with the hypertensive arterial disease. The more carefully controlled recent studies of thiocyanate therapeutics are almost unanimous in concluding that the drug is distinctly dangerous, the toxic reactions are so severe that the danger from the therapy is greater than the danger from the disease for which it is administered.

The most common manifestations of thiocyanate intoxication are muscle weakness, papular dermatitis, nausea and vomiting, slight (but never marked) fever, disorientation and mental confusion, aphasia, delirium, convulsive seizures, coma and death. These phenomena appear usually in the order given, with increasing severity of the intoxication. In a recent carefully controlled study of thiocyanate therapy in hypertension by Goldring and Chasis (*Arch Int Med* 49:321 [Feb] 1932), thiocyanate was administered to fifty patients, of whom thir-

teen (26 per cent) showed evidence of intoxication and two of the thirteen died. The dosage employed was conservative, less than 1 Gm daily. It was discovered that intoxication occurred in some instances when there was little retention of the drug within the body. Individual susceptibility appears to be a prominent factor in determining the severity and outcome of thiocyanate intoxication. Experimental studies on the toxicology of thiocyanates (Nichols J. B. *Am. J. M. Sc.* 170:735 [Nov.] 1925) revealed brain and spinal cord changes similar to those which occur in severe intoxication in man. Small doses, such as from 0.065 to 0.13 Gm thrice daily, usually fail to cause any appreciable fall in the arterial tension. With doses up to 0.3 Gm thrice daily, satisfactory reduction of the arterial tension is obtained in about half of the patients.

It may be concluded that sodium or potassium thiocyanate (it appears immaterial which salt is employed) is not fully satisfactory for the management of hypertensive disease. In dosage adequate to be effective in reducing the arterial tension for any length of time, the likelihood of dangerous intoxication is considerable. The probable detriment outweighs the probable benefit when one considers the results from a broad and unbiased point of view. Certainly the amounts prescribed by the first physician as cited, are entirely unwarranted. A study of the rate and completeness of the excretion of the salt in this patient would have been interesting and probably instructive. Thiocyanates give a deep red in an acid solution when treated with ferric chloride. This color may be used for quite accurate quantitation colorimetrically when compared with the color developed from a solution of thiocyanate of known strength.

PHYSIOLOGIC EFFECTS OF WINES WITH MEALS AND DIETARY RITUAL

To the Editor—Is there any physiologic reason for serving different wines with each course at a full dinner? In other words does the taking of these wines and digestion improve the appetite or what? The following is an item which I am quoting from the December 1933 *Home and Field* page 171. As a pre-dinner appetizer then instead of a cocktail a very dry sherry or plain vermouth either served with or without bitters. For oysters a dry white wine and with soup if you wish you may serve dry sherry though it should be hardly repeated if it has been used as an appetizer. For the fish a dry white wine either a Burgundy one of the dry Bordeaux such as Graves or a Rhine wine. For the entree a light red wine either Burgundy or claret or even a fine white Burgundy. For steaks or roasts and all game a good heavy Burgundy or claret must be served. For desserts which are not too sweet a Sauterne a demi-sec champagne port a sweet sherry or Madeira. With coffee nuts fruit and cheese port sherry, or Madeira may be served. Please omit name.

M D, New York

ANSWER—The only ingredient in alcoholic beverages that so far has been shown to have action on the digestive processes is the alcohol itself. Alcohol in quantities that do not lead to acute or chronic gastritis acts as a stimulant to the gastric glands and hence increases the output of gastric juice. This is not due to the taste of alcohol or to the local action of alcohol in the stomach, because the same effects are produced by alcohol injected intravenously or administered by rectum.

But it is also established that the flavors in foods and drinks, to a person accustomed to such flavors and finding them enjoyable, can also increase the secretion of gastric juice by a complex reaction in the central nervous system. This has been shown certainly for food flavors and probably also obtains for the flavors of alcoholic beverages, although the latter has not been definitely proved. Repeated sippings of various kinds of alcoholic beverages with the different courses of a meal may thus tend to prolong this appetite gastric juice secretion factor beyond that produced by a single such ingredient, because it is well known that the taste for a substance or the enjoyment of the taste soon fades on repetition. Such continued action of the appetite gastric juice secreting mechanism would be significant only in persons with decreased gastric secretory mechanism, because, normally, more gastric juice is secreted during a meal than is actually needed for gastric digestion.

The alcohol itself in moderate amounts has, of course, another indirect effect on digestive processes, due to a general relaxation of bodily tensions and mental strain, both of which act unfavorably both on gastric secretion and on gastric motility. But the elaborate practices of taking different types of alcoholic beverages alleged to be particularly suited to certain types of foods is largely a built-up dietary ritual similar to the rituals in religion. That is to say persons not accustomed to these habits digest their food well in their absence. But when once established the mental distress and disagreeable feelings due to the absence of such dinner accessories may for a time tend to decrease the gastric juice during the meal until "reeducation" has been established in the individual.

ULTRAVIOLET ERYTHEMA—PRURITUS ANI— ALLERGIC DISORDERS

To the Editor—I am writing to you to get your opinion on some medical matters pertaining to myself. I have an ultraviolet ray burn on my left leg between the ankle and the knee, over the shin or front of the leg. There are several patches or areas raised above the level of the skin about the thickness of a postcard just like scar tissue. That part of the leg was treated with ultraviolet rays for supposed ringworm three or four years ago resulting in this condition. I am annoyed by the intense itching over these areas. I scarcely know what to do for it any more. As I have used everything I can think of and what my colleagues and dermatologists have prescribed for it and nothing so far has stopped it. The remedy that gives me the most relief is 10 per cent phenol (carbolic acid) in petrolatum and that only temporary. Do you know of any cruet or escharotic I could use to destroy the sentient nerves in those areas without producing an ulceration of the parts? Or would you recommend surgery and excise the areas a part at a time and when that heals up excise another and so on until the whole thing is cut out? I also am a victim of pruritus ani. The intense itching is as bad as the leg. What can you suggest for that? The same ointment gives the most relief but doesn't stop it. I also have an enlarged prostate giving considerable trouble. Is there any drug or prostatic extract I can take orally to reduce the size, like thyroid extract for goiter? Or would you advise transurethral resection? I will give you this information, which may help you to give advice. I have been a victim of spasmodic asthma. I have that trouble practically under control. I find I am sensitive to proteins especially wheat protein and sometimes bacterial pus germs and the pneumococcus predominating. These conditions have practically all cleared up by my avoiding the wheat foods in my diet and I have been feeling fairly comfortable all the time for the last two years. Some of the doctors here say I am allergic whatever that is but that doesn't help me any although I have a fairly good opinion of what allergy is. Now a little kindly advice from you may help me in these troubles.

M D, Ohio

ANSWER—While it is risky to attempt diagnosis or therapy by mail it is permissible to give a tentative opinion based on the description. It would be a rare thing for ultraviolet radiation to cause the condition mentioned on the leg. A dermatologist probably can make a diagnosis on inspection or by investigation. He may be able to cure or relieve the condition with x-rays (if they have not already been used) or by topical remedies or both. Especially as the patient is of an allergic type it would be too hazardous for any one to prescribe even local remedies without seeing the condition and noting the effect of remedies prescribed.

As a rule, x-rays judiciously administered by an expert will stop anal itching in about a month and with absolute safety. But before doing this, the possible causes of the condition should be checked—local causes, such as ringworm general causes, such as diabetes intestinal parasites, hemorrhoids, and fistula or fissure, foci of infection or dysfunction of the nervous system. It is possible, but not probable, that the enlarged prostate might have something to do with it.

The treatment for enlarged prostate depends on the cause and the type. Prostatic massage and other physical therapeutic methods may be beneficial for some types, while surgery is necessary for other types. It is advisable to consult a genito-urinary specialist for this condition, because treatment prescribed without an examination might produce harmful results.

We regret our inability to give specific advice. The only possible advice that we can give is necessarily in the nature of general suggestions.

TREATMENT OF NITROGEN GAS POISONING

To the Editor—Kindly inform me as to the present treatment of cases exposed to or overcome by nitrous gases such as nitrogen monoxide nitrogen trioxide and red fuming nitric acid. Is oxygen-carbon dioxide indicated in the more severe cases and are there any contraindications for its use at any time? Is ammonium carbonate or any compound that might liberate alkaline fumes of any value if administered at once? Kindly omit name.

M D Indiana

ANSWER—The treatment called for in conditions resulting from the action of nitrogen gases is far more extensive than that directed solely to edema of the respiratory tract. The following suggestions are made:

1 Although impairment usually is delayed for ten or twelve hours exposure occasionally is immediately followed by failure of various brain centers and prompt prospective death. In these few cases, early administration of artificial respiration and oxygen-carbon dioxide is needed. If the affected individual survives, he may be in need of some or all of the subsequently suggested measures.

2 Promptly after exposure to any of the nitrogen gases and without waiting for any impairment, complete rest should be procured and oxygen should be administered, but not necessarily oxygen-carbon dioxide mixture. The violent respiratory excursions occasioned by carbon dioxide (7 per cent) is undesirable. Oxygen alone is most helpful, and carbon dioxide should be avoided unless necessary to stimulate respiration. The use of

atropine in moderate doses may be advantageous. In about two out of seven cases, tracheotomy may be required.

3 Systemic disease may ensue, resulting from the action of absorbed nitrites. The cardiocirculatory system and the kidneys may be damaged. The administration of 50 per cent dextrose solution is warranted. Very early supportive treatment should be extended to the heart. Measures increasing the viscosity of the blood are not commendable.

4 Pneumonia and other infectious processes of the respiratory tract are frequent. All procedures should contemplate the probability of such events.

The action of nitrogen gases, after entering the respiratory tract, is almost instantaneous. Theoretically, there may be a time when the administration of alkali vapors, fumes or gases is desirable. Practically, this is not the case, as already the local damage to tissues has taken place and neutralization has been provided by the formation of nitrates and nitrites. For this reason the use of ammonium carbonate, ammonia or related substances is not recommended.

Treatment of these conditions is further discussed by Zangger in brochure 69 of the International Labor Office's Encyclopedia of Occupation and Health.

PEMPHIGUS IN MOUTH

To the Editor—Mrs D, a Russian Jewess aged 61, has had recurring bullae on the hard palate for five months. These bullae are flaccid, occur every two or three weeks and rupture very easily in from six to eight hours with a bloody discharge. There is some pain after the rupture but no odor and there results a clean looking ulcer with a definite red border which heals with no scarring. To date these lesions have appeared only on the hard palate. Careful search has revealed no bullae on the skin or in the vagina. A diagnosis of pemphigus was confirmed at a large hospital. Physical and laboratory examinations give essentially negative results except for hypertension varying from 150 to 180 systolic and 95 to 100 diastolic. The patient has no teeth. Roentgen examination shows no retained roots or other pathologic condition of the upper or lower jaws. Examination of the sinuses gives negative results. Treatment at present is a high caloric high vitamin diet, calcium gluconate and viosterol 1 drachm (4 cc) three times a day and injections of sodium cacodylate every other day. So far although the patient's general condition remains good there has been no improvement in the oral condition. Please use initials only. M D Massachusetts.

ANSWER—In a patient of 61, pemphigus beginning in the mouth has anything but a cheerful prognosis. Failure of treatment to control it is the rule. The diet now in use should be continued. Sodium chloride should be excluded, for salt retention is a feature of the disease. One of the substitutes obtainable from the druggist should be used in its place.

The Davis treatment, intramuscular injections of a hemostatic every other day and an intravenous injection of iron cacodylate on the alternate day, has relieved some cases. Alkalinization is highly extolled by some authorities. Arsphenamine, neoarsphenamine or tryparsamide, which have been successful in some cases, can be given only with the greatest caution to a woman of 61 with high blood pressure. Quinine by mouth or intravenously pushed to the physiologic maximum has long been used, with occasional benefit. High colonic flushings given daily for a long period have apparently cured some cases. Spontaneous improvement for a short or longer time occurs in pemphigus, so that the treatment must not be credited until the improvement has lasted for some time, or until a recurrence has again yielded to the same treatment.

SHOE CORRECTION FOR BOWLEGS AND KNOCK KNEE

To the Editor—What shoe corrections are advisable for bowlegs in infants and young children? For knock knee?

BERRYMAN GREEN M D Riverside Calif

ANSWER—The decision must be made according to the situation present in the individual child. If the feet are pronated, regardless of whether bowlegs or knock-knee is present, the tilting of the shoes should be made on the inner border of the heel.

In many cases, modification of the shoes is highly beneficial, in others correction of the deformity is a natural result coincident with treatment and growth. It is natural, when a limb grows in length, that it should grow straighter, unless there are some basic factors that prevent this natural self correction of deformity. It is well known that when nature corrects bowlegs it often overcorrects, producing knock-knee and vice versa.

The correction of bowlegs, which are often accompanied by inverted feet, i. e. moderate pigeon toes, may be accomplished by tilting the outer borders of the heel and soles to decrease the degree of inversion, supination, adduction or varus, i. e., to produce a very moderate degree of flatfoot.

In case of knock-knee, or genu valgum, which is usually accompanied by flatfoot, raising the inner border of the heel and sole is advisable for the first correction, then raising the inner border of the heel for the second correction, and, third, raising the inner border of the heel and outer border of the sole.

It may be difficult to evaluate the benefit derived from these measures, especially during a period of rapid growth.

The most common modification of the shoe is raising the inner border of the heel three sixteenths inch. The next most common is raising the inner border of the heel and inner border of the sole. The third most common is tilting the inner border of the heel and outer border of the sole.

FIBROSIS UTERI

To the Editor—To one, like myself who has spent nearly ten years in as large an institution as the Los Angeles County General Hospital and who has examined on an average of from five to six thousand surgical specimens a year for some years, the problem of the so-called fibrosis uteri is a real one and one that is not easily answered. Many uteri are removed that show comparatively little or no pathologic changes to account for the uterine bleeding said to have been present clinically and still the surgeon often falls back on the diagnosis of fibrosis uteri particularly when the uterus appears to be somewhat enlarged and the myometrium seems to be rather fibrous. Most of those uteri are multiparous and the enlargement is consistent with several pregnancies. Some pathologists have even gone so far as to report normal uterus back to the surgeons much to their chagrin. So now finally are there generally accepted criteria for the gross and microscopic features of fibrosis uteri?

LAWRENCE PARSONS M D, Reno Nev

ANSWER—Attempts to explain uterine bleeding on the basis of fibrosis uteri, arteriosclerosis of the uterine vessels, and kindred lesions, have always been unsatisfactory because the pathologic condition has been such a variable factor and not at all proportionate to the amount or character of the bleeding.

Even though the patient has an enlarged "fibrotic" uterus, the modern conception is that abnormal bleeding in such cases is attributable to disturbed function of the ovaries, the anterior pituitary or even other endocrine glands. The presence of a disproportionate amount of fibrous tissue is believed to be secondary or incidental rather than the primary cause of the abnormal flow.

Diagnosticians may have gone too far in ruling out fibrosis as a cause of hemorrhage, but it is certain that some factor in addition to fibrous changes plays a part in most of these cases.

VINCENT'S INFECTION OF MOUTH

To the Editor—A single man aged 25 in good general condition contracted Vincent's infection of the mouth in 1926. He has been treated on and off by several good dentists without cure. He has a horizontal impacted third molar on the lower right which with a malposed second molar has formed a focus for residual infection. He has had among other treatment local applications of 10 per cent arsphenamine in dextrose by the last dentist who treated him without appreciable improvement. That dentist referred him to me recently for intravenous therapy. I have to date given him three injections at five day intervals of 0.6 Gm of neoarsphenamine and two injections at the same interval of 0.9 Gm of neoarsphenamine. But smears taken at weekly intervals from the gums are still positive. His teeth are in excellent condition. The dentist believes that the impacted wisdom tooth and the second molar have caused an area of infection about those teeth and constitute the obstacle to overcome in effecting a cure. Do you think that it is reasonably safe to extract those teeth in the presence of the Vincent infection? Or what is the proper procedure in this case? Is there any new medicinal treatment? Should intravenous neoarsphenamine be continued and if so how many injections should be considered a good trial of this treatment? I am enclosing a roentgenogram of the impacted molar. Please omit name.

M D, Connecticut

ANSWER—From the report of conditions given, this is probably not a case of Vincent's infection, which is an acute condition with definite and positive clinical symptoms. 1 There is a rapid superficial necrosis. The surface of the tissue is covered with a greenish pasty mass, easily removed, exposing hemorrhagic or bleeding surfaces. It is rapidly progressive. If this were a case of Vincent's infection, the third molar shown in the roentgenogram would be entirely uncovered in a few days. 2 There is always a fetid, foul odor, which can usually be recognized at a considerable distance. 3 There is increased flow of saliva. 4 The temperature ranges from 100 to 101. 5 There is extreme malaise, weakness and depression. 6 There is usually mental depression.

Vincent's infection is an acute condition and there is no such thing as chronic Vincent's infection. This disease was described first by Dr T L Gilmer, who called it acute ulcerative gingivitis. He described in classic fashion its etiology and treatment.

The present case is probably a low grade mixed infection of the pockets surrounding this third molar. Fusiform bacilli and spirochetes can always be found in smears from such areas, but their presence is not diagnostic of Vincent's infection. After a few days' local antiseptic treatment it is probably safe to remove such a tooth, but not more than one such infected tooth should be removed at a time. This should, of course, be done under proper conditions and with proper after-care and supervision.

No new medical treatment for such cases has been recommended recently. Intravenous injection of neoarsphenamine has never been justified in the treatment of Vincent's infection, either theoretically or clinically, and has been generally discarded by the practitioners most experienced in the study and treatment of the infection.

ENDOCRINE ALOPECIA

To the Editor—A woman aged 21, has been shedding her hair for the last eight years. At times the hair will grow in somewhat but it will quickly begin to fall again. This began about the time of her first menstruation. Her scalp is dry and she complains a great deal of itching. There does not seem to be any dandruff. The pubic hair and that in the axilla is also sparse. She has had a good deal of trouble with menstruation which has been scanty about five days in duration and until lately painful. The flow at first is pale but at the end becomes bloody. There are no clots at present. Vaginal examination shows a small antero flexed uterus the ovaries are not palpable. The introitus is rather small even for a virgin. She is quite slender in build 67 inches (170 cm.) in her stocking feet and weighs 118 pounds (53.5 kg.). I have given her amniotin and thyroid internally which has improved the menstruation and lessened the pain and for a while seemed to stimulate somewhat the growth of hair. Lately I have been giving also tablets of the anterior pituitary body but to date have gotten nowhere. Can you make any suggestions as to treatment of this case? Please omit name.

M. D. Ohio

ANSWER—From the fact that this peculiar disturbance of hair growth began at puberty, it seems likely that some endocrine gland dyscrasia is responsible. The relief of the dysmenorrhea by glandular therapy supports this idea. If the alopecia in this case is to be ascribed to a disturbance of one of the endocrine glands, it seems much more like that due to thyroid deficiency than to any pituitary trouble. The basal metabolism should be determined, and if it is low or normal thyroid medication should be continued, frequent clinical examinations being supplemented by an occasional check of the basal metabolism. Local treatment should be kept up, stimulants such as sulphur salicylic acid, resorcinol monoacetate and the various tars being combined in an oily menstruum to counteract the dryness of the scalp. For instance:

	Cm. or Cc.
R. Salicylic acid	1.0
Resorcinol monoacetate	1.5
Precipitated sulphur	1.5
Ointment of rose water	to make 30.0
M. Sig. Rub into the scalp vigorously once a day	

In the description given there is no evidence of pituitary disturbance. If there was such evidence, it would be justifiable to hope for improvement in hair growth along with the beneficial effect on the other manifestations as a result of pituitary medication. In the absence of any sign of pituitary trouble the long drawn out, expensive and troublesome experiment seems hardly justifiable. Any such treatment must be kept up for months before an effect on growth of hair can be seen. The pituitary preparation should be given hypodermically.

SHREDS IN FIRST GLASS OF TWO GLASS TEST

To the Editor—What is the significance of the persistence of shreds in the first glass of the two-glass test six months or one year after the disappearance of all symptoms of (a) gonorrheal urethritis and (b) a non-gonorrheal urethritis in spite of prostatic massages and the passage of urethral sounds? What further treatment is indicated? What treatment in addition to prostatic massage twice a week should be given to a patient whose prostatic smear is loaded with pus cells and staphylococci? The patient is a white man, aged 32 who presents a history of having had two years ago a gonorrheal urethritis all the symptoms of which cleared up in six weeks after 15,000 potassium permanganate irrigation and 5 per cent silver nitrate instillations but which left both glasses of the two-glass test rather cloudy and containing many shreds. Stannoyl methenamine pyridium caprool and prostatic massages have been of no avail in permanently clearing both glasses of the two-glass test. The patient feels fine and has no subjective urinary symptoms. Please omit name.

M. D. Pennsylvania

ANSWER—The persistence of shreds in the first glass of a two-glass test means the presence of localized infection in the anterior urethra probably located in the glands or follicles. These localized infections generally respond to the passage of urethral sounds coupled with massage of the urethra on the sound. In view of the fact that local treatment has failed to

clear up the shreds, the urethra should be examined with the urethroscope and the infected glands and follicles localized. They are best treated with the high frequency spark through the endoscope.

In this particular case, massage of the prostate and heat by rectum are indicated and should be continued until the strip pings are free from pus on microscopic examination.

TREATMENT OF HYPERHIDROSIS

To the Editor—Patients occasionally ask me for an antiperspirant or deodorant and I am usually in the habit of referring them to the advertised preparations. I should like to have a prescription if you care to suggest one for this purpose that may be used in safety. Anything you have to say on this subject would be of interest to me and I have several patients who would also like your sanction or suggestions in this matter. Kindly omit name.

M. D. Massachusetts

ANSWER—The simplest remedies for local hyperhidrosis are lotions such as tannic acid or zinc sulphate in dilute alcohol, from 1 to 7 per cent. Alum may be used in the same way. The skin should be wiped dry and the lotion dabbed on and allowed to dry on. This may be done several times a day if necessary. A dusting powder should follow it. Salicylic acid, from 2 to 4 per cent, and benzoic acid, from 4 to 8 per cent may be used in the dusting powder or in ointment of rose water. A stronger application of more lasting effect is 25 per cent aluminum chloride in water. The part is wiped dry or washed with plain water. After the skin is dry, the lotion is dribbled on and allowed to dry on. The solution is quite acid, therefore no soap must be used before it is applied, nor must the clothing be allowed to be wet with it. It should be used only once in three days until the effect is obtained, then once a week to prevent recurrence.

Local irradiation with x-rays produces the most lasting result. One-fourth erythema dose of unfiltered rays is given once a week until a partial effect is obtained, then the treatment is suspended. Usually considerably more drying will take place within the next two weeks. If not sufficient more can be given but not more than enough to total two full erythema doses. No irritating applications should be used during or immediately after the course of roentgen treatment. If the trouble recurs even years afterward x-rays should not be used again if the full amount has been given during the first course.

FELSOL

To the Editor—I am in receipt of an eight page brochure entitled "Contribution to the Therapy of Bronchial Asthma" by Dr. M. Kaercher in which is extolled the preparation Felsol. I recall a previous statement in THE JOURNAL pointing out that Felsol is apparently secret in composition. I should like to inquire: Who is Dr. M. Kaercher and is he an authority in internal medicine?

M. D.

ANSWER—We have no record in our files concerning an individual named Dr. M. Kaercher either in the files dealing with licensed physicians or in the student file.

According to the brochure the composition of Felsol is now given as: Metozin 0.9 (Phenazone 0.25, Anilipyrine 0.4, Iodopyrin 0.25), Caffeine 0.1, digitalis and strophanthus glucosides 0.0015 and the alkaloid lobelia inflata 0.005 Gm. Tests made some time ago in the A. M. A. Chemical Laboratory indicated that the product contained an acetanilid derivative in addition to other products. It is our understanding that this product distributed by the American Felsol Company of Lorain, Ohio, was seized by the federal Food and Drug Administration, allowed to go by default and destroyed. The substance may be looked on as a shotgun type of mixture promoted in typical 'patent medicine' style.

YELLOWING OF HAIR AFTER PERMANENT WAVE

To the Editor—Several beauty shop operators on being asked about giving a permanent wave to a woman who has gray (almost white) hair say that if she has any acid in her system the hair will discolor. What do they mean by any acid in her system? Is there any basis for this idea?

I. E. Hill, M. D. Hannibal, Mo.

ANSWER—The permanent wave, so called is produced by moistening the hair with a strongly alkaline solution and then applying a considerable degree of heat. It seems to be difficult to avoid excessive heat, which injures the hair. This does not show so clearly in colored hair as in gray or white hair, which is apt to turn yellowish. The statement about "acid in the system" is an attempt to provide an explanation other than the true one in case the hair is yellowed by heat and protect the operator from the blame due her.

SUCTION CELL RETAINER IN TREATMENT OF
HERNIA

To the Editor—A patient with an inguinal hernia asked my opinion of the value of the suction cell retainer for nonsurgical management in place of the usual truss. This appliance is sold by John G. Homan of the New Science Institute of Steubenville, Ohio. I felt that it was of no value but would greatly appreciate any information you have concerning this appliance.

RENO A. AHLIN, M.D., Joliet, Ill.

ANSWER—The suction cell retainer apparently consists of a round pad usually made about the size of the palm of the hand. It is claimed to remain in place by means of the suction mechanism of the pad without the use of a strap. The pad is claimed to be satisfactory for retaining a rupture during regular daily wear. No difference is claimed for different types of rupture. For strenuous exercises, a similar retaining pad with a belt to go round the hips is made. The suction cell pad combined with strengthening exercises to the abdominal muscles is claimed to cure a rupture when cure is possible.

The general tone of the literature and testimonials is such as to lead one to infer much more than it is worth actually to claim on careful reading. This type of advertising has been deprecated by medical men and by most ethical advertisers. Probably no more can be expected of this method than from the use of a well fitting truss, if as much.

TREATMENT OF FIBROID TUMOR

To the Editor—A woman aged 45 married with one child 19 years old had the usual diseases of childhood. She has not been sick since menstruation ceased eighteen months ago except for hot flashes which persisted until this summer. Six months ago she noted a symptomless hypogastric mass. Examination showed it to be a fibroid. It has grown slowly until it is the size of two fists. There has been no bleeding nor any other symptom except for some constipation and a moderate gastric hyperacidity. Would irradiation be desirable in this case or would surgery offer a better result? Please omit name.

M.D., Ohio

ANSWER—Operative removal is the treatment of choice. Irradiation of pedunculated tumors is inadvisable because of the danger of necrosis. Palliation in such cases is inadvisable, the risk is too great.

'LIVER GROWN

To the Editor—In THE JOURNAL Oct. 28, 1933, you answer M.D. Pennsylvania who asks concerning the nature of the condition popularly known as liver grown. In Pennsylvania and in Ohio in the latter of which I had my early knowledge of folklore there was a term the lady gave to a condition that came after such an experience as the Pennsylvania physician mentions. This condition consisted of a soreness and stiffness about the middle of the body where are found the liver, the lower ribs and the diaphragm. This soreness and stiffness lasted for from a few hours to several days. This depended on the amount of violence done and the length of time consumed in the causation. In my locality the term liver grown was applied to this condition generally caused by the following experiences: long periods of crying, sobbing, hysterical giggling or laughing, running at a jog or dog trot for some time, being tossed up in the air and caught by a strenuous father while the child is wildly giggling, long rides on a poor trotting horse and such experiences as quoted in the doctor's question. I believe that the condition is an acute myositis of the diaphragm and the lower intercostals. This condition never comes during the course of some regular exercise or duty. It comes after some unusual occurrence as mentioned. I have never heard that medical advice was seriously sought for relief of the condition. I have searched for the condition in medical literature and have thus far found no answer.

IVAN I. YODER, M.D., Cleveland

TRACHOMA

To the Editor—In Queries and Minor Notes in THE JOURNAL, January 20, is a question from a physician concerning the treatment of trachoma. The question is signed M.D. Nevada. I should think it would be well to follow up your answer with a statement something as follows:

The condition as described by the physician in Nevada wherein 75 per cent of the pupils in the schools of a certain town are described as having trachoma resembles conditions that have been found in the past in other places wherein high percentages of the school children have been described as having trachoma. In such cases I have usually found that the condition that was thought to be trachoma was not trachoma but a benign folliculo- or follicular conjunctivitis. This may be the case in the Nevada town spoken of. I would be inclined to advise the physician to use a much milder course of treatment than chaulmoogra oil, the best being 0.25 per cent zinc sulphate for instillation in the eye, as it obviously would not be well to subject a patient with folliculosis to rather severe treatment. The instillation of zinc sulphate for a period of six or eight weeks would also help the physician to decide whether trachoma or some benign follicular disease of the conjunctiva was prevalent in the school children.

RHODE ISLAND, Providence, April 5-6. Dir. Dr. Lester A. Round, 319 State Office Bldg., Providence.

TENNESSEE, Memphis, March 26-27. Sec. Dr. H. W. Qualls, 130 Madison Ave., Memphis.

WEST VIRGINIA, Charleston, March 12. State Health Commissioner, Dr. Arthur E. McClue, Charleston.

WISCONSIN, *Basic Science*, Madison, March 24. Sec. Prof. Robert N. Bauer, 3414 W. Wisconsin Ave., Milwaukee. *Reciprocity*, Milwaukee, April 5. Sec. Dr. Robert E. Flynn, 401 Main Street, LaCrosse.

THE AMERICAN BOARD OF RADIOLOGY

New Examining Board for Certification of
Specialists in Radiology

The desirability of instituting a certifying board for radiology was brought to a head at the meetings of the American Medical Association and the American College of Radiology held in New Orleans in 1932. At that time committees were appointed by the College of Radiology and the Section on Radiology of the American Medical Association to investigate the advisability of forming such a board. At the suggestion of the Council on Medical Education and Hospitals, this matter was brought to the attention of the American Roentgen Ray Society, the Radiological Society of North America and the American Radium Society at their annual meetings, and each of these societies likewise appointed a committee to investigate the advisability of forming such a board.

The committees representing these five radiologic organizations met, June 11, 1933, in Milwaukee during the meeting of the American Medical Association, effected a preliminary organization and adopted the following recommendations to be presented to each of the five associations represented:

- 1 That it is the sense of this joint committee that a national examining board for radiologists be formed.
- 2 That it be recommended to each of the five societies here represented that three members be appointed by each of the societies to constitute a national examining board for radiology.
- 3 That the purpose of the board shall be the examination and certification of radiologists.
- 4 That the board thus formed be authorized to effect its own organization, elect officers, adopt rules of procedure and proceed to the examination and certification of candidates.

The foregoing recommendations were approved by each of the societies, namely, the American College of Radiology, the American Roentgen Ray Society, the American Radium Society, the Radiological Society of North America and the Section on Radiology of the American Medical Association. Three members were appointed from each of the societies to form the board.

The organization meeting of the board was held at the Palmer House in Chicago, Sept. 28, 1933, during the first American Congress of Radiology, and H. K. Pancost was elected president of the board and B. R. Kirklin secretary-treasurer. A committee consisting of W. F. Manges, A. C. Christie and John W. Pierson was appointed to draw up by-laws and secure the incorporation of the board.

The board met again in Washington, D. C., January 27 and 28, at which time by-laws and articles of incorporation were adopted. The following permanent officers were elected: H. K. Pancost, president; A. C. Christie, vice president; and B. R. Kirklin, secretary-treasurer.

The purposes of the board according to the by-laws are as follows:

(a) To elevate the standards and advance the cause of radiology by encouraging its study and improving its practice.

(b) To test the qualifications of those who profess to be specialists in radiology by arranging and conducting examinations of voluntary applicants for the certificate of the board and to issue certificates to those found qualified therefor.

(c) To prepare and maintain a registry of holders of the certificate of the board.

(d) To serve the public, physicians, hospitals and medical schools by furnishing lists of those who have received the certificate of the board and thus to assist in protecting the public against irresponsible and unqualified practitioners who profess to be specialists in radiology.

The rules of the board require that applications for certificate be made on a prescribed form to be secured from the secretary.

Each applicant must establish to the satisfaction of the board that he is of high ethical standing, that he is a graduate of a medical school approved by the board, that he is a member of at least one of the societies that appoint members of the board, that he has had satisfactory experience in the practice of radiology, and that he is a physician duly licensed to practice medicine.

The by-laws of the board provide that "each applicant for the certificate of the board shall be examined in such manner and under such rules as the Board may prescribe, due weight being given in each individual case to professional attainments, years of training and practice, teaching and other positions held." It will be understood from this that the board intends to fix the extent and the scope of the examination in each individual case. The successive steps in a complete examination are as follows:

1. Submission to the secretary of the prescribed application form properly filled out.
2. Submission to the secretary of reprints or original thesis.
3. Personal appearance before the board for oral and practical examination.

The candidate will be informed after each successive step what is further required of him.

The experience of the boards already functioning has been highly satisfactory, and it is the general opinion that they have served to improve conditions in each specialty represented. Based on their experience the following advantages may be expected from the functioning of the American Board of Radiology:

1. Certification by the board furnishes a criterion to both lay and professional groups for judging a radiologist's qualifications.
2. Hospitals and other organizations will gradually establish rules limiting service on their staffs to those certified by the board.
3. It will gradually tend to limit specialization to those who are qualified to practice this specialty.
4. National and other special societies will eventually limit their membership to those who hold the board's certificate.
5. The public will gradually become informed of the importance of choosing specialists who are certified by the board.
6. Physicians in choosing consultants and in referring patients will gradually turn to those who are certified and thus help to eliminate those who are not qualified to practice radiology.

The first examination will be held in Cleveland, immediately preceding the annual session of the American Medical Association in June.

All radiologists interested should write to Dr. B. R. Kirklin, secretary, Mayo Clinic, Rochester, Minn.

New Jersey Endorsement Report

Dr. James J. McGuire, secretary, New Jersey State Board of Medical Examiners reports 156 physicians licensed by endorsement during 1933. The following schools were represented:

New Jersey October Examination

Dr. James J. McGuire, secretary, New Jersey State Board of Medical Examiners reports the written examination held in Trenton, Oct. 17-18, 1933. Forty-two candidates were examined, 37 of whom passed and 5 failed. The following schools were represented:

School	PASSED	Year of Grad	Per Cent
George Washington University School of Medicine	(1932)	(1932)	80.1

Movies and Conduct By Herbert Blumer Associate Professor of Sociology University of Chicago Cloth Price \$1.00 Pp 257 New York Macmillan Company 1933

Movies Delinquency and Crime By Herbert Blumer Associate Professor of Sociology University of Chicago and Philip M. Hauser Instructor in Sociology University of Chicago Cloth Price \$1.50 Pp 233 New York Macmillan Company 1933

Motion Pictures and the Social Attitudes of Children By Ruth C. Peterson and L. L. Thurstone Professor of Psychology University of Chicago [Combined with] *The Social Conduct and Attitudes of Movie Fans* By Frank K. Shuttleworth and Mark A. May Cloth Price \$1.50 Pp 75 142 with illustrations New York Macmillan Company 1933

These books are part of a series entitled "Motion Pictures and Youth," financed by the Payne fund. They are psychological and sociological studies, carried out by specialists in the fields of psychology and sociological research who, as a rule, have not been known for their interest in moving pictures per se. The first volume, entitled "Movies and Conduct," is a study based on the life histories obtained from university students in various parts of the country, and high school students in Chicago. It was found that the influence of moving pictures is ambivalent as far as modifying states of existence is concerned. In some cases it was found that such traits as beautification, mannerisms and courtship technique were modified by the movies, and fantasies can be definitely linked up with the motion picture experiences of boys and girls. A number of examples are given in which the picture either had no effect or a negative effect in these respects. The question whether emotional excitement, and other influences commonly attributed to moving pictures, do have the effect they are supposed to have has not been solved by this study. The author points out that motion pictures do actually influence human conduct.

The second volume treats of the influence of the movies on crime. The impression has always been that moving pictures are an incentive and inspiration to crime and, by using the same technique as that used in the previous volume the writers were able to show that this impression could not be entirely justified as far as the conscious knowledge of the subjects was concerned. However Blumer and Hauser say that "it seems clear that the motion pictures were a factor of importance in the delinquent or criminal careers of about 10 per cent of the male and 25 per cent of the female offenders." They found too that "on the other hand movies may redirect the behavior of delinquents and criminals along socially acceptable lines and make them hesitant about, and sometimes deter them from, the commission of offenses." Sometimes, however, "they do not have such a desirable effect."

The third volume is a combination of two reports treating of the relationship of the motion pictures and social attitudes. In the first, the case studies were made by the use of the "attitude scale." This is a psychological technique consisting of a list of statements, on a given topic, such as whether war is good or bad, which covers the whole field of possible attitudes toward that topic, from extreme conservatism to extreme radicalism. The subject is then required to check those statements which he believes to be true. These were given to the subject before and after his seeing a moving picture. For example, the attitude scale toward crime and punishment was given before and after a group of college students saw the picture "The Criminal Code," and it was found that there was a change in their attitude toward leniency in the punishment of crime. Studies of attitudes toward war, toward the punishment of criminals, and toward the Negro were thus made. In general, the results showed that a single picture might not have any effect on children but that two or more pictures had a cumulative effect. There was some evidence that the influence of motion pictures on the subject's attitudes persisted for some time after his seeing the picture. The second essay in this volume, dealing with the attitudes of "movie fans," consists of several studies in which various factors, such as reputation with the teacher or classmates, moral judgments, and social attitudes, are investigated by special tests to show the effect of movie going on the possessors of these factors. Data were also secured, by means of tests, determining children's attitudes toward such subjects as people of other lands, crime and criminals. The authors found that "from the data thus far presented it is apparent that the movies are only one of a larger number of factors which determine the attitudes and conduct of school children. That the movies are an influence there is no doubt." They discuss, in a general way, the theories behind the influence of the motion picture. The work has been well conducted according to the techniques used in the field on which they are based. However, the techniques themselves are open to criticism, chief of which is the fact that the autobiography method does not reach the subconscious changes and has no safeguards for the truthfulness of the statements given, and the psychological tests are susceptible to community and other random influences which may swing the results either one way or the other, and which cannot be controlled by statistical means. The fact that these authors are so well known for their technical ability and scientific honesty should weigh against chance error, and this is borne out by the extremely conservative conclusions which they draw. The first two of the monographs are readable, and all three contain much meat for those who are interested in the subject of the influence of the motion pictures, but the results emphasize the need for more research. Physicians, pediatricians and psychiatrists who are often asked their opinion about the influence of the movies, and those who are confronted with this problem, will probably find these books helpful to them in discussing the "movie problem" with anxious mothers.

Manuel de neurologie Tome I L'anatomie du système nerveux Une tentative de grouper en système fonctionnel les voies et les centres de localisation diverse par lesquels les diverses impressions sensorielles peuvent se traduire en réactions réflexes Par le Dr. Cornelis Winkler Part 5 Le corps strié et le diencephale Tome I Opera omnia Paper Price 35 francs parts 1 5 Pp 367 with illustrations Haarlem de Erven F. Bohn \ V 1933

The treatise on the anatomy of the nervous system, which even after the appearance of this fifth part remains incomplete, represents an attempt to group in functional systems the pathways and centers by which various sensory impressions are able to produce reflex reactions. This volume is limited to a consideration of the corpus striatum and the thalamus, hypothalamus and other parts of the diencephalon. The author is emeritus professor of neurology and psychiatry at the University of Utrecht, and because of his long and distinguished career any contribution from his pen is worthy of serious consideration. In the introduction he states that this book gives an account of the central nervous system as he sees it. One is therefore not disappointed in failing to find in it an adequate discussion of recent contributions by others to the field which it covers. Nevertheless, it is unfortunate that in more than 150 pages devoted to the diencephalon there is no mention of

the fundamental contributions by Huber and Crosby and their pupils Gurdjian and Rioch, or of the painstaking researches of Le Gros Clark. There is no bibliography. Some of the author's own observations are likely to meet an unfavorable reception on the part of neurologists. He describes in considerable detail a system of ascending fibers arising in the cervical spinal cord and brain stem and running to end in the putamen and globus pallidus.

Organic and Bio Chemistry. By R. H. A. Plimmer D.Sc. Professor of Chemistry in the University of London at St. Thomas Hospital Medical School. Fifth edition of *Practical Organic and Bio Chemistry*. Cloth. Price \$7.50. Pp. 624 with 70 illustrations. New York & London: Longmans Green & Company, 1933.

In this edition the theoretical considerations of the organic chemistry section have been extended and additions have been made to the section on physiologic chemistry. The book offers a full course on the theoretical and practical phases of the subjects, brought down to date. Many practical, well chosen experiments appear throughout the text. A list of general and special reagents is appended. The simple systematic presentation of the subject matter makes this book an especially helpful general reference work for the student, the teacher and the physician.

Taxes Clinic Not Exempt from Taxation.—The Lois Grunow Memorial Clinic Inc., of Phoenix, Ariz., sought to restrain the assessment and collection of taxes against its real and personal property. There was a judgment against the clinic in the trial court and an appeal was taken to the Supreme Court of Arizona.

The Arizona statutes exempt from taxation corporations not organized for profit formed for research, investigation and experimentation in scientific subjects. Buildings used for educational purposes and charitable institutions for the relief of the indigent or afflicted are also exempt. Such statutes exempting property from taxation, said the Supreme Court of Arizona, are to be strictly construed. The presumption is against tax exemption. The evidence in this case, continued the court, discloses that while some charitable practice is done individually by the several physicians and surgeons who rent and occupy offices in the clinic building yet each pays rent and conducts his own business for a profit and makes charges for his professional services. The fact that these physicians and surgeons rent space in the clinic building and conduct their private practice therein in no way differentiates them from any other physician or surgeon who does likewise in connection with his practice elsewhere. Nor, continued the court, do the highly commendable charitable acts on the part of the individual physicians and surgeons who occupy offices in the clinic building inure to the clinic in such a way as to constitute it a charitable institution within the purview of the Arizona statutes. It cannot be said that the building and equipment of the clinic are used for charitable purposes, nor can it be said that they are not used for profit. Whether or not profit is in reality derived from the business there conducted is beside the question. The test is whether or not the building and equipment are used in an effort to derive a profit therefrom, if possible. The evidence conclusively shows that the building and equipment of the clinic are being used by those who rent space therein in connection with the practice of their professions for the very obvious purpose of deriving a profit therefrom.

An educational institution, the court said, has been judicially defined as "one which teaches and improves its pupils, a school, seminary, college or educational establishment." The court could find no support for the contention that the property of the clinic was being devoted to educational uses or purposes in such a way or to such an extent as to render it exempt from taxation or that such property was being used for purposes of scientific research. The evidence did disclose that some scientific research had been undertaken by those connected with the clinic, but whatever may have been done in that respect the court said, was merely incidental to the general activities of

the clinic and was not such as to establish it as an institution for scientific research not conducted for profit. The Supreme Court of Arizona concluded, therefore, that the real and personal property owned by the clinic was not exempt from taxation and the judgment of the trial court was affirmed.—*Lois Grunow Memorial Clinic v. Oglesby (Ariz.)*, 22 P. (2d) 1046.

Hospitals, Charitable Liability for Burn with Hot Water Bottle.—A hospital conducted for benevolent and charitable purposes is not liable to a patient for the negligence of its servants and employees unless it is shown that the hospital was guilty of negligence in the employment or retention of the offending employees or servants. A charitable hospital, however, may be liable for the injuries inflicted on an employee arising out of and in the course of his employment with the hospital. In the present case the plaintiff, a patient in the hospital, received a burn on her leg from a hot water bottle placed in the bed, apparently by hospital nurses. She sued the defendant hospital, an institution organized and operated for charitable purposes. The trial court directed a verdict for the hospital. In affirming the judgment based on the directed verdict the court of civil appeals of Texas said that, while the evidence was sufficient to justify submission to the jury of the issue of negligence on the part of the nurse, there was no evidence warranting the conclusion that the hospital failed to prescribe proper rules of government or was negligent in the selection or retention of the offending nurses.—*Steele v. St. Joseph's Hospital (Texas)*, 60 S. W. (2d) 1083.

Privileged Communications Fact of Medical Attendance Not Privileged.—Section 14216, Compiled Laws of Michigan 1929, provides that no licensed physician shall be allowed without his patient's consent to disclose in court any information which he may have acquired in his professional character in attending any patient which information was necessary to enable him as a physician to prescribe for such patient. This statute said the Supreme Court of Michigan, was enacted to prevent the abuse of the confidential relation existing between the physician and his patient and is for the patient's protection. It covers information acquired by observation while the physician is in attendance on his patient, as well as communications made by the patient to him. Consequently, in an action to enforce payment under an insurance policy it was proper for the trial court to refuse to permit physicians who treated the insured to testify with respect to the insured's ailment and to restrict their testimony to the fact merely that they had treated the insured.—*McKinney v. Liberty Life Ins. Co. of Illinois (Mich.)*, 248 N. W. 881.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Granulosa Cell Tumors of the Ovary—According to Schulze, granulosa cell tumors of the ovary are frequently mistaken for medullary carcinoma, or for sarcoma or endothelioma. There are three main histologic types, the folliculoid, the cylindromatoid and the sarcomatoid. Frequently, two or all three of these types are found in different areas of the same growth. The clinical diagnosis may be easy before puberty or after the menopause but is difficult during active sexual life. A careful study of the patient from the endocrine standpoint will prove of great aid in the preoperative diagnosis of these cases, as well as in the postoperative prognosis. There is definite evidence that these tumors elaborate the ovarian follicular hormone and possibly, in some cases, the lutein hormone also. It is probable that the follicular hormone tests will become as important for these cases as is the Aschheim-Zondek test for chorionepithelioma. These tumors are usually unilateral and comparatively benign, and simple excision of the tumor is ordinarily curative. Therefore it is most important to make a preoperative or at least an operative diagnosis, as this permits conservative treatment in the case of young women. In women past the menopause, the complete removal of the pelvic organs is preferable if the patient is a good operative risk. In the rare cases in which complete removal of the tumor is not possible, postoperative radiotherapy will probably increase the chances for cure.

Eclampsia Treated by Injections of Magnesium Sulphate—Lazard discusses the intravenous magnesium sulphate treatment of 575 cases of preeclamptic toxemias and eclampsias of which 371 were preeclamptic and 225 convulsive toxemias. He concludes that in view of the varied etiologic factors which may produce the eclamptic syndrome, it is in all probability impossible ever to obtain a specific cure for eclampsia. The objectives of treatment in the preeclamptic state should be (1) to overcome the effects of the toxemia by sedation and elimination, (2) to remove as much work as possible from the embarrassed excretories by proper regulation of the diet with particular reference to balancing the fluid intake

with the output, and (3) to terminate the pregnancy as conservatively as possible, when there is no proper response to treatment, before the onset of convulsions. The chief objective of treatment of the eclamptic patient should be the control of the convulsions and the protection of the patient against accidents during the convulsions and coma, surgical termination of the pregnancy during the eclamptic attack is justified only in patients in labor who present some urgent obstetric indication. The necessary sedation and elimination is best secured by intravenous magnesium sulphate in sufficient dosage, aided by intravenous injections of dextrose. The gross mortality for the author's entire series, preeclamptic and eclamptic patients, was 5.9 per cent. The gross mortality for the active eclamptic patients was 13.33 per cent, and the corrected mortality 9.5 per cent.

Treatment of Prolapse of the Uterus—Shaw states that a combination of anterior and posterior colporrhaphy with amputation of the cervix is the best method of treatment for all cases of prolapse of the uterus. This operation is the best for all patients having this condition, whether young or old, parous or nulliparous. In the author's series of 549 cases, 529 (95.35 per cent) were cured. This operation is not a cause of trouble in subsequent labors. The prolapse may recur after subsequent labors, but in less than 25 per cent of cases. It is necessary to combine an abdominal operation with the colporrhaphy only in those rare cases in which practically no muscular tissue is found in the pelvic floor. The author resorted to this procedure in only two cases.

Diagnosis of Intestinal Tuberculosis—Gauss and his associates state that there are no pathognomonic signs of intestinal tuberculosis. The high incidence of intestinal tuberculosis reported by pathologists includes a considerable number of terminal lesions and is to be differentiated from clinical tuberculosis which produces morbidity. The diagnosis is suggested by the failure of any patient to make satisfactory progress

when the pulmonary lesion is quiescent or improving. The common symptoms of intestinal tuberculosis are diarrhea, abdominal pain, abdominal tenderness, abdominal rigidity and cramps after eating. The roentgen evidence of intestinal tuberculosis includes the presence of spastic filling defects in the ascending colon, hastened emptying time of the colon, dilatation and segmentation of the small intestine, ileac stasis and/or gastric retention. When a person presents some of the signs and symptoms or roentgen evidence and is known to have pulmonary tuberculosis, a clinical diagnosis of intestinal tuberculosis may be made. However, in adults in the absence of pulmonary tuberculosis, one would hesitate to diagnose intestinal tuberculosis. Since the direct diagnosis is based largely on evidence of hypermotility and ulceration of the intestinal tract, the differential diagnosis must be made from pathologic states that give rise to hypermotility or ulceration of the intestinal tract, which include protozoal infection, bacterial infection of the colon, tumors of the intestine, disorders in the formation, position or configuration of the colon, appendicitis, digestive, nutritional, rectal and endocrine disorders, blood dyscrasias, cardiorenal disease, industrial poisons and surgical complications. The authors report a study of 125 patients in a tuberculosis sanatorium who presented gastro-intestinal problems. These were classified under twenty-seven different clinical entities. The nontuberculous states are far in excess of the tuberculous states, being in the approximate ratio of 5:1. The majority of gastro-intestinal problems encountered among patients in a tuberculosis sanatorium are nontuberculous rather than tuberculous. Postmortem examinations indicate a reasonable agreement between clinical and postmortem diagnoses. Intestinal tuberculosis was found principally in patients living far advanced pulmonary tuberculosis.

Vioosterol and Tuberculin in Healing of Tuberculous Lesions.—De Szytsch and his associates observed that the use of a combination of viosterol and tuberculin in the treatment of moderately advanced tuberculosis in guinea-pigs gives definitely beneficial results, as judged by longevity, the degree of tuberculous involvement and the amount of fibrosis. The optimal effect of the treatment is apparently obtained when the viosterol and tuberculin are given simultaneously rather than when one precedes the other by forty-eight hours. The average life span of animals receiving simultaneous treatment with viosterol and tuberculin is markedly increased as compared with that of the tuberculous controls or of the tuberculous animals treated with viosterol alone or tuberculin alone. The average degree of tuberculous involvement in animals receiving simultaneous treatment with viosterol and tuberculin and in those treated with viosterol followed in forty-eight hours by tuberculin is considerably less than that of the controls or of the animals receiving tuberculin followed in forty-eight hours by viosterol. The average amount of fibrosis in animals receiving the combined treatment of viosterol and tuberculin is definitely greater than that of the controls.

Bone Marrow in Agranulocytosis.—Jaffe discusses the histologic changes of the bone marrow in nine cases of agranulocytosis. Five of the cases belong to the group of the so-called idiopathic form. Two seemed to have developed during antisyphilitic treatment, while the remaining two proved to be cases of prolonged *Streptococcus viridans* septicemia. In agranulocytosis the essential pathologic process is a disintegration of the specific granules of the myelocytes which is followed later by pyknosis of the nucleus and death of the cells. Because of the disappearance of the granulation, the myelocytes lose their characteristic appearance. The degeneration of the myelocytes

is sometimes preceded by proliferation. In a considerable number of cases of agranulocytosis the giant cells of the bone marrow show signs of proliferation and degeneration which suggest relations to the other forms of regressive blood dyscrasia, in particular to aleukia haemorrhagica. The changes of the bone marrow indicate that agranulocytosis is a symptom complex rather than a disease entity.

Malignant Neurinoma (Schwannoma) with Epithelial Elements.—Brandes reports the case of a solitary tumor occurring in the thigh with many features similar to schwannomas. The clinical features were severe pain in the thigh of a duration of five months and rapid increase in the size of the tumor. Histologic study indicated that epithelial-like structures were the most important elements of the tumor and that they in part at least if not entirely gave rise to the stroma. The rapid growth and the associated degeneration were probably important in the production of metastases.

Spontaneous Renal and Ureteral Fistulas.—Higgins and Hicken present a case each of spontaneous nephrocolic, nephroperirenal, renocolic, ureterovesicoperitoneal and ureteroperiureteral fistula and state that spontaneous renal and ureteral fistulas are the result of advanced kidney disease such as tuberculosis, nephrolithiasis, pyonephrosis, hydronephrosis or neoplastic disease and occasionally arise from perinephric abscess secondary to caries of the vertebrae, perityphlic abscess, pelvic disease or peripheral infections. The diagnosis is made on the basis of the clinical symptoms, corroborated by cystoscopic and roentgenographic studies. The most important consideration in the treatment of spontaneous urinary fistulas is prophylaxis, the prevention of advanced kidney diseases to the stage of fistula formation by the use of early corrective measures. Closure of a renal fistula usually requires nephrectomy as the kidney is so generally diseased that practically no functioning tissue remains. In cases constituting a grave surgical risk, conservative measures are indicated, primary drainage of a perinephric abscess usually results in improvement, so that a nephrectomy may be performed later. The use of indwelling ureteral catheters may facilitate the repair of a ureteral fistula, but usually the kidney is harboring infection which has destroyed the parenchyma to such an extent that its conservation is useless.

Intussusception and Tuberculosis.—Easton suggests that every tuberculous patient be regarded as a potential victim of intussusception and his treatment planned with this complication in view. This may mean simply an intensification of the regular treatment for tuberculosis with special emphasis on overnutrition, protection from overexertion and an increased watchfulness for gastro-intestinal symptoms. In cases of pulmonary tuberculosis it is a complication to be feared since it may not only lessen the possibility of recovery by interfering with the patient's nutrition but in its acute form is more than

likely to precipitate a fatal termination. On the other hand, pulmonary tuberculosis, with its weakening effect of the gastrointestinal tract, predisposes the patient to intussusception. Undernourishment, through an insufficient or ill balanced diet, is a definite causative factor and perhaps the only one through which effective preventive action may be taken. The author reports a case of intussusception in which the immediate cause of death was tuberculous bronchopneumonia, localized peritonitis, necrosis of the ileum and old intussusception. The direct cause of the intussusception could not be determined as there was no neoplasm or tuberculous ulceration at the site of the lesion.

Ribs Overlying Empyema Cavities—Bisgard describes the structural changes commonly observed in ribs overlying empyema cavities and the relation of these changes to the parietal pleura and presents certain deductions relative to the pathogenesis of these changes based on clinical, histologic roentgenographic and experimental data, which indicate that the transformation has been brought about by the inflammatory response or periostitis, which probably is most active during the acute stage of an empyema, and a functional response in which the osteogenic elements of these ribs bring about certain transformations in accord with the principles outlined in Wolff's law. It would appear that the greatest abnormal force acting on these ribs overlying chronic empyema cavities is the centripetal traction of the contracting pleural scar. To resist this force, the transformation of the inner architecture constantly observed in the specimens examined would logically be anticipated.

Complement Fixation Test in Carcinoma—Saphir and Hirschberg applied the complement fixation test for carcinoma to twenty-seven serums of cancer patients and eighty-two control serums. The tests were positive in 77.7 per cent of the twenty-seven serums and in only one of the eighty-two control serums. A patient having lobar pneumonia gave the positive reaction. The authors are of the opinion that the reaction is of a physiochemical nature due to the influence of the antigen on the serum globulins rather than a specific antigen-antibody reaction. The clinical value of the reaction awaits further observation after refinement and a better understanding of the nature and the limitations of the test. The technique of the complement fixation test for cancer parallels the original Wassermann technique in one-tenth amounts being a five tube quantitative test with incubation at 37°C.

Serum Albumin and Globulin of Infants—Darrow and Cary determined the serum concentration of total protein, albumin and globulin in twenty new-born fourteen normal,

aged about 5 months, and twenty-six premature infants. They made similar studies in full term and premature infants suffering from various diseases. They found that the total protein is decreased in all infants, the decrease being due chiefly to low globulin. The diminution in globulin is greatest in premature infants. Postmortem serum of small fetuses shows essentially the same albumin-globulin ratio as that of full term infants. Both premature and normal infants may show an increase in globulin during infection. The authors suggest that the low globulin in infants may indicate the lack of the usual stimuli that give rise to globulin production in adults.

Whooping Cough Treated with Gold Tribromide—Epstein observed that gold tribromide was an effective remedy in cases of whooping cough. Treatment consisted in the oral administration of a solution of gold tribromide in water. The dosage varied with the age of the child and the severity of the paroxysmal cough. Generally, from one-twentieth to one-tenth grain (0.003 to 0.006 Gm.) was given after meals and at midnight. The author found that a solution of gold tribromide in water did not keep well on standing and he now uses chloroform gold tribromide (a teaspoonful three or four times a day). In about two thirds of his whooping cough patients, the cough subsided in three weeks, in the others, it abated within from five to seven weeks. In all cases, after a treatment of three or four days with gold tribromide, the cough was less frequent and less distressing, the attacks were shorter and milder, the vomiting ceased and sleep was more restful. There were no recurrences, complications or fatalities in this series of cases. In twenty-five controls who received the usual antipertussis remedies, the cough was frequent and racking and the course of the disease varied from three to four months.

Cystoscopic Prostatectomy—Foley describes a new instrument and method that represent a radical new departure from the punch principle. An electrode projected far beyond the sheath lumen and operated under accurate visual control permits rapid excision of practically any desired extent of the obstructing gland, amounting in fact to "cystoscopic prostatectomy." The radial incisions are made first. In this process bleeding is controlled by alternating the cutting current with periods of coagulation. Particularly in the bottom of each incision, thorough coagulation should be employed. During operation of the electrode, continuous "down draft" irrigation is used. A brisk stream of fluid is supplied from an irrigating tube surrounding the telescope and opening above the vesical neck, with a continuous return flow down the urethra and through the sheath. This carries any bleeding from the incision downward and minimizes interference with vision. By the use of either retrograde or foroblique telescopes in the working element, vision may be had of the incision either on the vesical neck side with the periphery of the gland in view or up through the urethra with the intra-urethral surfaces of the lobes in view. After the radial incisions have been made and the bleeding in each one has been controlled, the sections of gland between them are cut away by rotation of the whole instrument. In making this circular part of the excision, the cutting element describes a conoidal surface of rotation. Except for their rotation in making the circular incision, the sheath and

retrograde telescope remain in fixed position in relation to the vesical neck during the whole procedure and the peripheral part of the enlarged gland is always in the visual field without a change in the magnification, as would occur if there were alterations in the level of the objective lens above the vesical neck. When the foroblique telescope is used, the lower end of the electrode is at the lower edge of the field and the telescope moves with the electrode, giving vision from down in the urethra upward through the vesical neck with the whole electrode in the field. The author states that, from the cases in which operation has thus far been performed, it appears that, if bleeding in the radial incisions has been adequately controlled, only slight bleeding will occur from the circular or rotating incision. The excised pieces of tissue may be divided into smaller pieces with the electrotome forceps and may be removed from the bladder with the grasping forceps. When the procedure is completed, a 26 F catheter is fixed in the urethra. The author concludes that in the hands of the competent cystoscopist a majority of prostatic obstructions can be relieved by cystoscopic prostatectomy or by transurethral prostatic resection and that removal of the gland by a major operation is justified only in a limited number of cases. A comparison of transurethral resection with suprapubic prostatectomy in identical groups of material has shown that the clinical results with resection are as good as those obtained by suprapubic operation, while the postoperative mortality is less.

Two-Way Resection of Large Prostates—Ballenger and his associates present a two-way resection method, which is particularly indicated when large vesical calculi or diverticuli coexist with massive prostatic hypertrophy. With the patient in the Trendelenburg position, retractors are placed so as to hold the bladder away from the protruding mass. A large curved Cameron light is used. A tube, ordinarily used in tonsil operations, is attached to the suction apparatus employed to remove urine and blood. When the protruding prostate is exposed, pieces are resected, with suitable loops, until the intravesical mass is removed. Bleeding is stopped by fulguration as the resection proceeds. After sufficient tissue has been taken away and all bleeding stopped, a large retention catheter is placed in the incision, which is closed as usual, a Penrose drain being left in the prevesical space. Within a week or so, under low spinal anesthesia preferably with a brand of procaine hydrochloride containing strychnine sulphate transurethral resection is carried out. The suprapubic mushroom catheter is clamped and pulled up until its head is against the anterior wall of the bladder. The subsequent management and time of removing the suprapubic tube varies according to the condition of the patient and complicating factors. Less than 5 per cent of prostates require this method, as transurethral resection in one or two stages can be done by competent resectionists in more than 95 per cent of obstructions.

Carcinoma of the Prostate—Dillon outlines a procedure for carcinoma of the prostate in which the prostate is exposed through the perineum by the usual technic and enucleated in its entirety by an inverted V incision in the prostatic capsule, the entire prostatic urethral mucosa being removed from the membranous urethra to the neck of the bladder. In the advanced cases in which the prostatic capsule is infiltrated, the growth is shaved off, a sufficient thickness of capsule being left to form a new prostatic urethra. In a few cases with marked infiltration into the seminal vesicles, the growth was partially removed by following the ejaculatory ducts in the posterior flap, but it was found that this procedure caused delayed healing and closing of the perineum, owing to the large cavity produced. Infiltration around the neck of the bladder should be carefully trimmed off and any induration in the region of the middle lobe or suggestion of a median bar should be removed. Bleeding of the neck of the bladder is controlled by interrupted catgut ligatures. Two rubber tubes containing 50 mg of radium each, in four 25 mg ampules spaced according to the size of the prostatic capsule are placed in the regions of each lateral lobe, on each side of the perineal drainage tube and urethral catheter in the bladder. The posterior flap containing the posterior lobe, is brought up and sutured at its apex between the radium tubes. The rectum is separated from the pelvic fascia well below the level of the radium tubes and the

space packed with iodoform gauze at least a half inch in thickness, covering the entire prostatic capsule to the membranous urethra. The radium tubes, the bladder drainage tube and the gauze packing are brought out together on the right side of the perineal wound. The radium tubes are left in place from ten to fourteen hours, giving from 1,000 to 1,400 mg hours of crossfire irradiation to the wall of the bladder round the vesical neck and the posterior flap containing the posterior lobe, as well as irradiating the lateral walls of the prostatic capsule. The author presents this method as a palliative measure that will give the greatest comfort and relief of urinary symptoms for the remainder of their existence in patients suffering from carcinoma of the prostate.

Vitamin B Deficiency in Adults—Elsom presents a case in which definite symptoms followed a voluntary restriction of diet. The symptoms strongly resembled those of pernicious

anemia marked pallor, glossitis and symptoms and signs of posterolateral sclerosis. The typical observations of pernicious anemia, achlorhydria and anemia were lacking. When liver was administered in a dosage adequate to produce a remission in pernicious anemia there was no response, with the exception of some improvement in the glossitis. When vitamins B₁ and B were administered there was rapid improvement in the fatigue, anorexia, dyspnea, vertigo, paresthesias, edema, glossitis, scaling of the forearms and brittleness of the nails. This improvement began in two weeks and was complete at the end of six. The author concluded that the patient's symptoms and physical signs were due to a deficiency of the vitamin B complex. The improvement of the glossitis during liver therapy is believed to be due to the fact that liver contains measurable amounts of vitamin B. The close resemblance of many aspects of this case to the characteristic picture of pernicious anemia suggests some common factor between the two. At no time did the patient show anemia or detectable impairment of gastric secretion. It has been noted that pitting edema of the lower extremities disappeared with vitamin B therapy. The plasma proteins rose to a normal figure regardless of the fact that there was no increase in the protein of the diet. It seemed possible that the vitamins might be responsible either for increased absorption or for increased utilization of protein already present in the diet. This is believed to be important since it suggested a cause for edema not found in the usual etiologies of cardiac or renal disease, low protein intake, or the failure of the absorption of protein secondary to gastrointestinal disease. Detailed studies are at present under way in an effort to determine the exact explanation for the occurrence of this edema as well as of the symptoms described.

Effect of Analgesics on Arthritis—The observations of Rawls and his associates indicate that palliation of pain is usually accompanied by unmistakable clinical improvement, as judged not only by the signs and symptoms but also by a reduction in the sedimentation rate and the shift to the left in the nuclear count. In the cases in which these effects were noticed the authors employed solely as analgesics a combination of magnesium and amidopyrine, as suggested by the work of Barbour and Winter, and amidopyrine, as suggested by Leher.

Treatment of Chorea by Induced Pyrexia—Cheetham treated four cases of chorea by induced pyrexia. The treatment consisted of the daily intravenous administration, for a period of from seven to ten days, of TAB vaccine in sufficient quantity to produce a temperature of from 103 to 106 F. The vaccine contains 1,000 million *Bacillus typhosus*, 750 million *B. paratyphosus A* and 750 million *B. paratyphosus B* organisms in 1 cc. The initial dose is 0.1 cc intravenously, which almost invariably produces a satisfactory response. There is a severe constitutional reaction. The patient vomits and develops a peculiarly cyanosed appearance. The choreic movements are markedly increased for the time being. Subsequent doses are increased in accordance with the response to the first injection. An approximate rule is to double the dosage each day. The final dose may be as much as 25 cc. Sutton recommends the administration of acetylsalicylic acid and an icebag to the head if the temperature rises above 106 F. With careful attention to dosage, however, this is a rare incident and did not occur at any time in the author's cases. The injection is given in the early afternoon to enable the subsequent reaction to subside before night and thus not to interfere with the child's sleep. The constitutional reaction becomes less marked with each injection, until the final injection produces no obvious reaction apart from the pyrexia. The author observed that the treatment of chorea by artificial pyrexia shortens the duration of choreic movements, does not prevent recurrence and appears to have no beneficial action on rheumatic carditis. Its grave danger lies in the tendency to produce a false impression of cure by abolishing the movements, which in themselves are merely a symptom, when serious changes may be occurring in the heart. The author does not allow a child with acute rheumatism out of bed as soon as the joint swellings have subsided under the influence of salicylates. In the same way it is undesirable to allow a child out of bed two weeks after the onset of an attack of chorea unless it can be conclusively proved that the treatment which cuts short the choreic movements also cuts short any accompanying carditis. When these facts are borne in mind, it is clear that the use of artificial pyrexia has a limited place in the treatment of chorea.

Aural Vertigo Treated by Ossiculectomy—Dundas-Grant is convinced that in suitable cases ossiculectomy is of the utmost value. It does not do away with the necessity for the radical mastoid operation, but in certain cases presenting symptoms indicating radical procedure the operation of ossiculectomy has relieved these symptoms and shown the radical operation to have been avoidable. Ossiculectomy should be considered before such operations as obliteration of the labyrinth or section of the eighth nerve on account of vertigo are undertaken. Often the practiced eye will detect changes attributable to retractions of the membrane or fixation of parts produced by the residue of inflammation in the middle ear. In some of the twelve cases that the author describes the ossicles obstructed

the outlet of the attic and prevented the escape of thickened discharges or cholesteatomatous collections and in others their fixation led to immobility of an otherwise mobile stapes. In the former the removal of the ossicles permitted the free escape of contents of the attic, with relief from vertigo and headache and, to some extent, from dullness of hearing. In the latter the restored mobility of the stapes provided the normal safety valve for variations of intralabyrinthine tension, with a disappearance of the distressing vertigo. He concludes that, in the normal subject, such removal would probably reduce the hearing to about 6 feet for the soft whisper, a useful but a much diminished amount of hearing power. In a patient having a greater degree of hearing, ossiculectomy would therefore be undesirable unless called for by a major disability, the removal of which rendered a moderate reduction of hearing a matter of relatively minor importance. In most of the cases in which ossiculectomy is required the hearing power is less than this and the operation, while making it no worse, sometimes makes it better than before, as in one of the author's cases.

Action of Atropine in Complete Heart Block—Gilchrist tested the response of ten persons suffering from complete heart block to the intravenous administration of $\frac{1}{30}$ grain (0.002 Gm.) of atropine sulphate. Repeated electrocardiograms taken at intervals before and after the injection, demonstrated that this drug produced an acceleration of the ventricular rate. The dose of atropine was sufficient to produce almost complete paralysis of the vagus. The maximal increase in the ventricular rate was 47 beats per minute, representing a gain of almost 96 per cent over the initial rate. The minimal acceleration was 12 beats per minute, giving an increase of 54 per cent. In only one case was the gain after atropine within the maximal range recorded under similar resting conditions. At low initial rates, atropine produces but little acceleration. The coefficient of correlation between the rate before atropine and the amount of ventricular acceleration produced by it is +0.97. The use of atropine as a means of distinguishing the bradycardia of complete heart block from that of other causes is therefore unreliable. Further work must be done on this subject with the object of determining the precise nature of the response to atropine in those cases of slow heart action in which complete heart block is not present. To obtain a decided effect on the ventricular rate, it is necessary to use an amount of atropine approaching the full paralyzing dose, $\frac{1}{30}$ grain of atropine given intravenously in 1 cc of physiologic solution of sodium chloride was found to be sufficient. The auricular range after atropine does not bear any relation to the ventricular. The amount of auricular acceleration varies irregularly in each individual. The auricular response probably reflects no more than the degree of vagal tone existing at the moment of injection. The nature of the ventricular response suggests that the amount of acceleration is determined by the inherent rhythmicity of the specialized tissue at the center of impulse production. The author suggests that when the lesion producing the block is situated in the uppermost part of the conducting tract, a greater response will occur after atropinization than when the center of impulse production lies at a lower level in the specialized tissues. As a converse, vagal stimulation is more likely to be effective in slowing the idioventricular rate when the center of impulse production lies high in the conducting tract.

Action of Epinephrine in Complete Heart Block—Gilchrist observed the reaction of twelve patients suffering from complete heart block to repeated subcutaneous doses of epinephrine. Acceleration of auricles and ventricles may occur within two to four minutes of the injection. The amount of ventricular acceleration induced bears a striking relationship to the rate existing immediately before the injection. High

initial rates are followed by little or no gain in rate, slow rates by pronounced acceleration. The gain in rate after 0.25, 0.75 and 1 cc of epinephrine is similar to that recorded after 0.5 cc. In other words, for a given initial rate 0.25 cc. of epinephrine will produce as much acceleration as a dose four times that amount. The independence of the size of the dose and the response recorded suggest that a surface action is involved and that epinephrine is being adsorbed on some (? enzyme) surface, as an essential condition of its action. The observation that the initial rate determines the degree of acceleration finds support in blood pressure studies. It has not been found possible to demonstrate as close a correlation between the initial auricular rate and its increment after epinephrine as that observed in the case of the ventricles. The auricular response is modified to some extent, particularly in those cases in which the magnitude of the ventricular response is maximal, that is, when the initial ventricular rate is relatively low. It would appear probable that reflex vagal influences, induced by a marked ventricular reaction, limit the auricular response. The amount of limitation is apparently determined largely by the initial ventricular rate. The reaction to a subcutaneous dose of epinephrine varies as much in complete heart block as it does in the normal beating heart. The maximal auricular and ventricular reactions are not necessarily synchronous. As a general rule, the auricles attain the height of their reaction before the ventricles have completed their acceleration. An increased frequency of both chambers of the heart persists after the blood pressure rise has returned to its preexisting level. No untoward symptoms resulted from the employment of the drug. Reactions differing from the foregoing were encountered in four patients. One suffered from intermittent complete block. When tested during complete block no change occurred in the rhythm, but a branch defect changed from one side of the heart to the other. Tested during 2:1 rhythm, complete block was induced. The direction of the main ventricular deflection varied according to the presence or absence of conduction through the main stem of the bundle. During half-rhythm the ventricular complex in lead 3 was directed downward whereas during complete dissociation its direction was upward.

Anemia, Cell Volume and Blood Iron Estimation—To compare the value in diagnosis of the color index, cell volume index and iron index, Fullerton and his associates made a full hematologic investigation consisting of 129 observations in pernicious anemia, fifty-seven in idiopathic microcytic anemia, forty-one in posthemorrhagic anemia and fifty-seven in other anemias. They observed that in all types of anemia and at all stages the indexes run parallel to one another. The cell volume index and particularly the iron index, gave higher readings than the color index. The advantages claimed for these methods in the diagnosis of macrocytic hyperchromic anemia are confirmed but they are offset by an increased difficulty in the diagnosis of microcytic hypochromic anemia. Accordingly, the color index, if accurately estimated, still remains a simple and satisfactory procedure for routine diagnostic purposes, but for difficult cases and research work the addition of one or both of the subsidiary methods affords a valuable check. The authors present the results of investigations into cell diameter, blood pigments and iron metabolism.

Ayerza's Disease—Castex and his co-workers state that chronic bronchopulmonary lesions are of greater importance in the genesis of Ayerza's disease than lesions of the pulmonary artery. The disease may occur with or without arteriosclerosis of the pulmonary artery, but the sclerotic lesions of the pulmonary circulation are important as evolutive factors because, by increasing the work of the heart, they accelerate its insufficiency. The disease cannot develop if the patient is not previously affected by a protracted bronchopneumonia, but the clinical syndrome is seldom observed in these conditions whether associated or not with sclerotic lesions of the pulmonary artery. The basic lesion a bronchopneumopathy of any kind, must lead to such a deficiency of alveolar air content as to create a reduction of at least 15 per cent of oxygen in order to produce cyanosis as the first stage of the evolution of the disease. It is also necessary that the individual possess a bone marrow capable of reacting by polyglobulism to direct or indirect stimuli, constituting a compensatory mechanism through which the organism may secure sufficient oxygen for the needs of the tissues despite the fall in the alveolar tension of this gas. Patients whose erythropoietic organs are incapable of offsetting the bronchopulmonary process inducing anoxemia cannot present the clinical picture of this disease. This explains why the majority of patients are afflicted with the disease in early youth rather than in advanced age. Thus, despite the frequency with which the protracted bronchopneumonic diseases are observed in elderly patients, the pathologic syndrome of black cardiac is seen only exceptionally. The constitutional peculiarities explain why, in spite of similar pathologic conditions so few persons develop the syndrome.

Paroxysmal Tachypnea of Decubitus—Cibils Aguirre and Araoz report the case of a girl, aged 9 in whom decubitus caused instantaneously a crisis of paroxysmal tachypnea and bradycardia. The respiratory rhythm before and after the crisis was normal but was accelerated in decubitus to from 120 to 150 respirations a minute. The pulse rate which before the crisis was 120 a minute was retarded to between 78 and 86 pulsations during decubitus. The disappearance of the crisis was as rapid when the child sat up as its appearance had been when she reclined. During sleep the respiratory movements were from 24 to 28 a minute and the pulse was 70. Except for a slight corticopleuritis there were no other pulmonary and bronchial symptoms. A roentgenographic study of the thorax showed tracheobronchial adenomediasitis which the authors diagnosed as being of tuberculous origin based on the positive results of the Mantoux test on the presence of corticopleuritis and on the fact that the child lived in intimate contact with her sister who died from pulmonary tuberculosis. That the tuberculous adenomediasitis was the cause of the respiratory and pulse syndrome by a compression of the pneumogastric

nerve was proved by the results from the functional tests of the vagosympathetic system, by the symptoms given by the patient and by the symptomatologic exclusion of the sympathetic nerve in its mediastinal course. The authors failed to find any similar case in the modern literature. In the classic literature, however, they found a relation between decubitus and the changes of the respiration and the pulse explained as being caused by compression of the pneumogastric nerve during decubitus by swollen mediastinal nerves.

Delayed Callus Formation Resulting from Antiseptic Treatment of Wound—Boerema studied the results of treating compound fractures in pigeons and in hens with and without antiseptic solutions, with particular regard to the question of delayed callus formation. He cut across the radius of a pigeon separated the periosteum, and then held a pledget soaked in a 5 per cent solution of tincture of iodine or a 3 per cent solution of phenol in contact with the fragments for about three minutes. The wound was then closed by suturing. An identical procedure was repeated on the corresponding opposite side without, however, the use of antiseptic solution. Roentgenologic control, as well as histologic studies, demonstrated conclusively a marked delay in callus formation in every bird in which antiseptics were used. In some instances necrosis of soft tissues or of a bone fragment took place. The author believes that retardation of callus formation was due to the effect of antiseptic solutions on the specific bone building tissues, the cambium layer of periosteum and the endosteum. The use of a solution of 3 per cent hydrogen dioxide as well as of iodoform gauze did not have, in his experiments, the effect of delaying callus formation.

Claudication Venosa Intermittens of Upper Extremity—Intermittent claudication of venous origin affecting the upper extremity need not be due to an actual thrombosis of the axillary or the subclavian veins, according to Lohr. He differentiates a special clinical entity in which the syndrome was due to venous stasis. The condition presents an analogy to the intermittent claudication of the lower extremity, with the difference that in the lower extremity muscular activity becomes arrested because of insufficient arterial blood supply, while in the upper extremity the same phenomenon is caused by the inadequate return of the venous blood. Intermittent claudication in the lower extremity does not occur without a simultaneous thrombotic closure of the main vein, while in the upper extremity this is not necessary. Muscular contractions in the lower extremity drive the venous blood toward the heart, while in the upper extremity they retard the return of venous blood. It appears, therefore, that the conditions for the venous return are less favorable in the upper than in the lower extremities. Because of narrowness (in the physiologic sense) of the subclavian vein, it is not necessary, in order to produce venous stasis, for the vein to be obstructed by a thrombus, as hard muscular work may produce it by causing backflow. The functional demands on the lower extremities, however, are so much greater than those of the upper that the actual incidence of the vascular diseases in the former is much greater than in the latter. The immediate relief in the objective and subjective signs and symptoms on the completion of operation is a definite proof of the existence of types of venous claudication due to minor hindrances of the return flow in the axillary cavity. These types must not be confused with those caused by throm-

basis of the large veins. The patients operated on made a rapid recovery. For patients not operated on, anatomic restitution and functional recovery are a matter of months, at times of a year. The author believes that the incidence of intermittent claudication due to venous stasis is probably greater than that due to thrombosis of the axillary or the subclavian veins. The most important etiologic factor in this group is an unaccustomed, unusual, prolonged muscular effort, the effect of which is to dilate and overstretch the axillary or the subclavian vein. Among the contributing factors are mentioned enlarged axillary lymph nodes, compression of the dilated vein by fascial strands of the costocoracoid fascia, tumors, subscapular bursitis, large callus of a recent clavicular fracture, goiter or lung tumor. The author observed thirteen patients of this type. Four were operated on by him for what was considered classic thrombosis of the axillary vein. No thrombosis was found. The vein in three cases was partly constricted by fascial strands. The differential diagnosis of the two types presents many difficulties. The distended axillary vein may easily suggest a thrombosed vein. However, patients with real thrombosis are usually elderly, either debilitated by malignant disease or presenting a severe trauma and infection. Characteristic for the syndrome described is that the patients are younger persons in the best of health, that the onset is sudden, that they have no fever or infection, and that they show a normal blood count and a negative Wassermann reaction. The patients give a history of prolonged, unaccustomed hard muscular strain. The condition does not give rise to embolic phenomena and serious complications. Signs of stasis disappear after the development of collateral circulation. The author cites his own four cases and Wulsten's, one case as a definite proof of the existence of venous stasis without thrombosis because in all five the absence of a thrombosis was demonstrated in the course of the operation. Operative treatment is recommended for all cases.

Lymphogranulomatosis.—On the basis of 103 cases of lymphogranulomatosis (Hodgkin's disease) studied at the Leningrad Oncologic Institute Munkin arrives at the following conclusions: 1. Lymphogranulomatosis is a rather common disease of the reticulo-endothelial system, especially of the portion located in the lymph nodes. 2. The disease presents a symptom complex not present in any other chronic disease of the hematopoietic system. 3. Included in this symptom complex are a progressively increasing lymphopenia, monocytosis and increase in neutrophils, while the colorless blood elements remain unaltered, itching of the skin, prurigo, bronzing of the skin and eczematous eruptions. The temperature curve presents characteristic fluctuations consisting of periodic alternations of high temperatures of an irregular type with afebrile periods. The involved glands are of an irregular consistency, and the skin over them is not adherent or fistulous. The involvement of the lymph nodes is always progressive and not a simultaneous process. The disease runs a severe clinical course with fatal termination on the average after from two to three years. 4. The author differentiates three histologic types: (a) the productive inflammatory, (b) the hyperplastic and (c) the tumor forming. 5. The more frequent type is the productive inflammatory, characterized by polymorphism and pleomorphism of the cells, fibrosis and areas of local necrosis. 6. However, even in this type there are found in some of the lymph nodes involved alterations of a more simple character consisting of hyperplasia of the reticular cells alone without fibrosis and admixture of hematogenous elements such as lymphocytes and polymorphonuclear leukocytes. 7. Hyperplasia of the reticulo-endothelium was the only alteration found in the lymph nodes in a number of the cases. These types cannot be differentiated from the so-called reticulosis. It is quite possible that a number of cases described in the literature as reticulosis were in reality a hyperplastic form of lymphogranulomatosis. 8. Because the lymphogranulomatous tissue may invade the neighboring structures and penetrate vessels, one is justified in speaking of a blastomatous type of lymphogranulomatosis. This applies particularly to the hyperplastic monomorphic type, difficult of differentiation from reticulocytomas and similar tumors. 9. The giant cells of Sternberg develop from the reticular cells, more rarely from the endothelial cells of the sinuses of the lymph nodes.

Infection and Vaccination in Tuberculosis.—Since 1924 Heimbeck has studied the tuberculous infections found in the nurses of the communal hospital of Oslo. The experience gained during the first three years, was an inducement to extend his studies to the population of Oslo. He reaches the conclusion that only a small minority of persons contract tuberculosis during childhood, the majority becoming infected in later life. The disease manifestations of tuberculosis appear as a rule shortly after the primary infection. The allergy that is detected by means of the Pirquet reaction is a sign of immunity, no matter whether produced by an attack of tuberculosis or by vaccination with BCG. In reporting his experiences with BCG the author states that, of 168 nurses who were vaccinated with it, eighty-four became allergic as a result of the vaccination before they were exposed to tuberculosis. Of these eighty-four, only one contracted tuberculosis, but of the other eighty-four who had not become allergic, eighteen contracted tuberculosis. This corroborates the author's opinion that allergy to tuberculosis is immunity to tuberculosis. Consequently if a BCG vaccination does not produce allergy, it has not conferred immunity and should be repeated.

Vitamin Content of Hypophysis.—Vogt examined ninety different hypophyses for their vitamin A content. He wanted to determine whether the vitamin content fluctuates, and particularly whether it influences the growth of malignant tumors. In summarizing his observations he states that the hormone activity of the hypophysis is dependent on a certain content in vitamin A. In chronic, exhausting diseases, such as sepsis, the vitamin finally disappears entirely from the hypophysis. The vitamin A content of the hypophysis is closely related to the growth of tumors. In the case of rapidly growing tumors the vitamin A content of the hypophysis is normal or increased, but in cancerous cachexia the entire vitamin A content of the hypophysis has been exhausted by the growth of the neoplasm and consequently is no longer demonstrable. The author suggests that the relatively slow growth of tumors in patients over 60 may perhaps likewise be a result of the depleted vitamin A content of the hypophysis. For the diet of cancer patients he concludes from this that, although care should be taken that it is of sufficient caloric value, it should not be too rich in vitamins. The mechanism of the interrelation between the vitamin content and the hormone production is not fully understood as yet. At any rate, the investigations have made it appear highly probable that there are close connections between hormones and vitamins.

Sugar and Acetone in Urine of Nondiabetic Children.—Altmann reports observations on the simultaneous occurrence of sugar and acetone in the urine of nondiabetic children. After

acetonuria had been produced by a diet deficient in carbohydrates, the children were given large amounts of dextrose. In a high percentage of the cases the author observed the development of glycoketonuria. It was regularly observed after a tolerance test in febrile acetonuria. The behavior of the blood sugar curve resembled that of diabetes mellitus. While the stomach was empty the blood sugar content was reduced after the ketogenic diet, but there was a tendency to hyperglycemia. The author was unable to obtain reliable results on the behavior of the acetone bodies in the blood following the tolerance test. After the ketogenic diet had been instituted, the development of the acetonuria required from twenty to ninety-six hours. There seemed to be no definite ratio between the acetone content of the urine and of the blood, respectively, and of the expiratory air. The author proposes two explanations for the glycoketonuria. 1. The content of acetone bodies in the blood changes only slightly after the sugar tolerance test and, for this reason, acetone continues to pass into the urine, and at the same time there develops an alimentary glycosuria. 2. Since the pancreas has become weakened by the abstinence from carbohydrates, the administered sugar cannot be sufficiently oxidized and thus cannot exert its anti-ketogenic function, that is, acetone continues to enter the urine. The hyperglycemia and the glycosuria are indications of incomplete utilization of the sugar. The therapeutic lesson taught by glycoketonuria is that, in spite of the fact that sugar appears in the urine, more sugar must be given to strengthen the pancreas. The author calls attention to the differences in the behavior of the temporary, artificially produced and the true diabetes mellitus but also points out that there are intermediate stages between the two and that a slight infection may be sufficient to turn the dietetically produced acetonuria into a true diabetic coma. This indicates that, in case of fever, acetonuria must be avoided. For unknown reasons the glycoketonuria does not develop regularly. The well known fact that a ketogenic, carbohydrate deficient, diet causes loss of weight was corroborated in these investigations.

Reversion of Hemolysis During Childhood—According to Erben it was Spiro who first called attention to the phenomenon known as the reversion of hemolysis. If to a varnish colored solution of blood corpuscles, which under the microscope appears free from erythrocytes, hydrophilic substances are added, the solution assumes color again, and pale but otherwise intact erythrocytes become once more visible under the microscope. Starlinger investigated the clinical significance of this phenomenon and found that in healthy persons the reversion stays within narrow limits (between 10 and 15 per cent) but that in patients suffering from blood diseases, particularly in those having pernicious anemia, the reversion is increased fluctuating between 20 and 40 per cent. The increase in reversion is most pronounced during the periods of increased regeneration while there is no increase during the aregenerative stages. Since many chemical and morphologic reactions of the blood of children differ from those in adults, the authors decided to study the phenomenon of reversion in children. He describes a micromethod for the determination of the reversion of hemolysis in the capillary blood. He employed this micromethod in tests on fifty-five children without blood diseases, on six normal adults and on twelve children presenting disturbances of the blood. In the healthy children and adults he obtained values between 15 and 25 per cent, the average being 19.8. Taking the ages into consideration, a maximum of reversion was noticeable during the first few weeks of life, but this decreased to a minimum during the second and third months. The author believes that with certain reservations this may be considered an indication of a reduced hematopoiesis at the end of the first three months of life. However, the material and the fluctuations are too small to permit definite conclusions. In secondary anemia of various origins, his observations tally with those of Starlinger in that an increase in reversion ran parallel with the intensity of the regeneration, and after regeneration ceased the reversion gradually assumed normal values again. He found that his micromethod gave somewhat greater fluctuations than did Starlinger's method and he ascribes this partly to the higher levels of the normal values in the micromethod and partly to the greater reactivity during childhood.

Necroses of Subcutaneous Fat Tissues in the New-Born—Bernheim-Karrer states that, since his previous report on necroses of the subcutaneous fat tissues in the new-born, he has observed fifteen more cases, a sign that the condition is not as rare as is generally believed. Of especial interest was one case because the necrosis was congenital, which proves that a prenatal trauma (perhaps pressure of the uterine wall) may cause a necrosis of the subcutaneous fat tissue, other cases were noteworthy because the fat tissues of the kidney were necrotic. These cases indicate that deeper lying fat tissues likewise may become impaired by the trauma of birth. Another important observation was that in several cases the necrosis ended in calcification. The author evaluates the different theories of the pathogenesis of necrosis of the subcutaneous fat tissues. He ascribes the greatest significance to trauma of birth. He shows that it may be the cause even in delivery by cesarean section, for circulatory disturbances, stases, hemorrhages and ischemia may cause necroses of the subcutaneous fat tissues. The trauma of injection has also been known to be the cause. That necrosis of the subcutaneous fat tissues is often absent in extremely difficult deliveries and occasionally is present in deliveries that are not so difficult may be due to the thickness of the layer of fat tissue. In support of this theory the author cites the fact that many of the children in whom necrosis developed were comparatively heavy at birth. But although the author considers the traumatic origin the most frequent one, he also admits other factors. He calls attention to observations reported by other authors, such as the concurrence of the fat necroses with calcium deposits, the presence of fatty acid crystals and certain resemblances with sclerema.

Tolerance to Levulose and Galactose in Premature Infants—Studies in which Fabisch and Etzold determined the threshold values for elimination in the urine revealed that premature infants have an average galactose tolerance of 16 Gm and a levulose tolerance of 15 Gm for each kilogram of body weight. Infants born at term have a galactose tolerance of 22 Gm and a levulose tolerance of 26 Gm. This shows that the liver of premature infants can utilize larger quantities of galactose than of levulose, while in mature infants more levulose than galactose is tolerated.

Measurement of Nuclei and Nucleoli in Malignant Tumors—In micrometric studies on the nuclei and nucleoli of nonmalignant and malignant cells, Haumeder found that in malignant cells the nuclei and nucleoli were considerably larger. But even when the nuclei were only slightly larger, the nucleoli showed a great increase in size. The ratio between the size of the nucleolus and the nucleus fluctuated in nonmalignant cells from 1/13 to 1/45 and in malignant cells from 1/5 to 1/17. Thus the enlargement of the nucleoli can be considered a characteristic of malignant cells. After pointing out that enlargement of the nucleoli in malignant cells has been demonstrated by several other authors (Quensel and Karp), the author reaches the conclusion that enlargement of the nuclei, and particularly of the nucleoli, is important for the early cytologic diagnosis.

Cancerous Diseases of Face—On the basis of observations on 500 patients with cancer of the face 247 of which

were examined histologically, Paljtschewsky reaches the following conclusions. Cancer of the face occurs nearly twice as often in men as in women. It is most frequent in farmers, and then follow workers who are exposed to various chemical and thermic influences. About 50 per cent of cancers of the face are basal-cell carcinomas. The aceratic forms of the spinocellular cancers predominate in younger patients, the basal-cell carcinomas are most frequent in middle age, and the canceroid forms predominate in the aged. The spinocellular cancers are found mainly near the natural openings of the face or at the border of the mucous membrane, and the basal-cell carcinomas at the sites where there are many sebaceous glands. A certain regularity in the development of cancer is undeniable and the location corresponds to the physiologic atrophies of the skin. As a rule, the spinocellular forms are preceded by lesions of the epidermis, whereas pathologic processes of the sebaceous glands or of the hair roots, or comedones, acne and nevus frequently are the precursors of basal-cell carcinomas. The varying behavior toward roentgen and radium therapy indicates considerable differences in the histogenesis of the different kinds of cancers.

Is Tomato Juice a Cancer Producing Factor?—Goldfeder treated sixty rats with tomato juice. Some of the animals were treated according to the method of Bellow, and others were given sterilized tomato juice either by intraperitoneal injection or by mouth. Malignant growths developed in none of the animals. However, at the site of the injection there always developed foreign body granulomas, abscesses and inflammatory granulation tissues.

*Genesis of Vesical Endometriosis. G. Haselhorst —p. 3021

*Vaginal Calculus in Congenital Urinary Incontinence with Double Formation of Vagina. B. Kriss —p. 3030

Genesis of Vesical Endometriosis—Haselhorst points out that, although there is considerable literature on the endometriosis of the bladder, the how and wherefore of the endometrioid proliferation have not been cleared up in most instances. In reviewing twenty-five cases from the literature he found three cases in which the vesical endometriosis was the result of a proliferation of the uterine mucous membrane through the scar of the uterine wall after Beutner's amputation of the bladder. In ten reports the anamnesis was incomplete, but, considering all cases, the author found an unusually high incidence of sterility. Myomatosis of the uterus was frequent among the patients, a sign that tendencies to connective tissue proliferation and to epithelial proliferation frequently concur. Disturbances of the adnexa likewise were frequent. Moreover, all except three of the patients had either had a gynecologic disorder or undergone a gynecologic operation. Not a single case has been reported in which it was established beyond a doubt that only the bladder was diseased. The localization of the endometriosis in the bladder is worthy of note. It is always the posterior portion of the bladder that is involved. The foci are, as a rule, between the orifices of the ureters or somewhat higher. There is no case on record in which the endometriosis was on the anterior wall or the free portion of the bladder. This seems to indicate that the section of the uterus adhering to the posterior wall of the bladder is principally the origin of the endometriosis. The author advises that the adjoining regions be searched for a focus in all cases of vesical endometriosis. He gives a detailed report of one case studied by him. On the basis of the histologic examinations he rejects the possibility of an invasion of the endometrioid epithelium from foci within the abdominal cavity, for a glandular connection between the cervix and the vesical wall was found in the center of the pedicle and the cervical glands and the endometrium shaded off into one another, a phenomenon that would be unexplainable if a proliferation from the outside was assumed. Moreover, the abundance of glands and

cysts in the cervical wall is a sign of a strong proliferative power in the glandular epithelium, whereas endometrioid foci were not found in the region of the pelvic peritoneum. Endometrioid proliferations were present also in the uterine tubes. Thus the case represents, on the part of the cervical glands and of the tubal epithelium, a tendency to proliferation beyond the physiologic limits, and the mucus forming epithelium of the cervical glands assumes an endometrioid character. The author sees the cause of this pathologic growth of the epithelium in disturbances in the hormonal equilibrium, and he thinks that these hormonal disturbances play a part also in the pathogenesis of sterility.

Vaginal Calculus—Kriss relates the clinical history of a woman, aged 30, who from early childhood had had urinary incontinence. Beginning with the tenth year she had had the feeling of a foreign body in the genitalia. At the age of 11, a stone (5 cm in length) was discharged. Subsequently calculary fragments were discharged from time to time. The patient married became pregnant at the age of 17, and had a normal child. A pregnancy, four years later, was interrupted. During all these years the urinary incontinence persisted and even became exacerbated as the result of the childbirth. Examination revealed a double vagina. The smaller one on the right side contained a number of small concretions. Roentgenoscopy of the spinal column revealed abnormalities in the lumbar region indicating spina bifida. Hysterosalpingography with the aid of contrast filling showed that the double formation did not involve the uterus and that the tubes were normal. The author explains the case in the following manner: The accumulation of urine in the nearly completely closed vagina led to the precipitation of salts and to concretion formation. Exertion (abdominal pressure) caused the calculus to be discharged. Following defecation the urine no longer could accumulate in the main vagina on the left side, whereas in the right accessory vagina the urine continued to gather, and thus there was still a possibility for the formation of small vaginal concretions. Not until the repair of the incontinence can the complete cessation of the formation of calculi be expected.

*Contribution to Knowledge of Prognosis and Treatment of Massive Hemorrhages in Gastric and Duodenal Ulcer. O. Mossberg —p. 897

Massive Hemorrhages in Gastric Ulcer—There was hemorrhage in some form in 46 per cent of Mossberg's 1,032 patients suffering from gastric and duodenal ulcer treated from 1922 to 1931 and manifest hemorrhage in 35 per cent. Of the cases of manifest hemorrhage 236, or 75 per cent, were more massive hemorrhages, and of these 90, or 38 per cent, were extremely grave. In 30 per cent of the patients presenting hemorrhage the ulcers were clinically acute (ulcers with history of up to one half year). There were 46 fatal cases of acute hemorrhage from 1912 to 1921, and 28 from 1922 to 1931 hemorrhage being the direct cause of death in most of them, with complications as a contributing cause in some. Necropsy in 35 instances showed that the anatomopathologic conditions did not always agree with the clinical picture and that in half of the cases the fatal hemorrhage was due to recent ulcers of the mucous membrane. The mortality from acute hemorrhage was 27 per cent of the total 1,032 cases, 9 per cent of the cases of manifest hemorrhage, 12 per cent of those of more massive hemorrhages, and 31 per cent of those regarded as extremely grave. When blood transfusion was given, the hemorrhage ceased in half the patients, mostly suffering from acute ulcers, some of these recovered. Operation was successfully performed on others after transfusion. Hemorrhages usually recurred after transfusion. The author states that operation is excluded in patients bleeding from a clinically acute ulcer, in patients having hemorrhage from clinically chronic ulcers with a pronounced longer history or in whom the ulcer has been located by earlier examination, especially in persons over 40, operation seems advisable and to offer good prospects if the intervention is made in so early a stage that the acute grave anemia from bleeding has not yet caused grave injuries to the internal organs.

TOBACCO, ALCOHOL AND ANGINA PECTORIS

PAUL D WHITE, MD
AND
TRIMBLE SHARBER, MD
BOSTON

The relationship of the use of tobacco and of alcohol to angina pectoris is a matter of widespread interest and great importance, and yet it continues to be merely a topic for idle speculation and medical gossip. No extensive and reliable data have been published to throw light on it, although occasional remarks and opinions have been expressed in accounts of this symptom of angina pectoris, or if statistics have been presented they have been either inadequate in themselves or else inadequately controlled. We have therefore considered it worth while to study one aspect of the subject by analyzing the habits in the use of tobacco and alcohol of a series of 750 patients of our own with angina pectoris as contrasted to the habits of a series of 750 individuals of the same sex and age incidence and from the same walks of life who did not have angina pectoris. The result of this study we are presenting in this paper.

LITERATURE

Tobacco and Angina Pectoris—Johnson¹ in 1929 reported that of sixty fatal cases of angina pectoris in males forty-two patients, or 70 per cent, were smokers, and eighteen, or 30 per cent, were nonsmokers. A control series of 1,000 men whose names were taken from telephone directories in five cities gave the incidence of smokers as 81.8 per cent.

Gallavardin² found that 27 per cent of 200 patients with nonsyphilitic angina pectoris had never smoked tobacco and that 4 per cent more had given up smoking years before their first attacks of angina pectoris, while only 18.5 per cent were immoderate smokers.

Lian³ from his own experience and from the literature has found that intoxication with tobacco is so often lacking in cases of cardiovascular pain and that the omission of tobacco has so feeble an influence on the evolution of the condition of angina pectoris that there is no reason to consider that the use of tobacco has any importance in the etiology of angina pectoris, he admits however, that the act of smoking, above all after a long interval without tobacco, may perhaps be the occasional cause of an attack. In his personal statistics of 800 cases of angina pectoris he has sought

in vain for a clear observation of tobacco angina, in two cases, tobacco seemed to be in part responsible for the appearance of angina pectoris.

Huchard⁴ cited four cases observed by himself in which angina pectoris was apparently excited by tobacco, other cases of the sort he borrowed from various authors, which confirms the impression that no one observer has encountered personally many such individuals.

In 1914, Pawinski⁵ asserted that tobacco was the most frequent etiologic agent in the production of "coronary sclerosis (angina pectoris)" in man chiefly because excessive smoking was found in 457 (41.9 per cent) of 1,075 men with coronary sclerosis as compared to obesity in 284 (26.3 per cent), the use of alcohol in 230 (21.3 per cent), and syphilis in 111 (10.3 per cent). In contrast to these figures he noted that among 2,081 cases of "arteriosclerosis not involving the coronaries" obesity headed the list at 540 (25.9 per cent), alcohol was second at 486 (23.3 per cent), tobacco third at 485 (23.3 per cent) and syphilis fourth at 282 (13.3 per cent). He quoted Bouchard's figures on the etiology of angina pectoris with 14 per cent smokers, Huchard's figures on causes of sclerosis with only 9.5 per cent smokers and Dunin's report on sclerotic patients of whom 48 per cent of the men and only 8 per cent of the women smoked to excess. Pawinski further stated that among women in his own series with angina pectoris excessive smoking was found in only 7.1 per cent (in contrast to the men with 41.9 per cent). It is evident from these statistics and from an analysis of his paper that Pawinski's conclusion that tobacco is the commonest cause of angina pectoris is unjustified.

Mackenzie⁶ in his monograph on angina pectoris did not mention the association with tobacco or alcohol except to refer to the old time treatment of an acute attack by an alcoholic drink. He has, however, in other publications referred to the well known fact that sometimes tobacco is apparently primarily responsible for the occurrence of premature beats. Tobacco has also been known to have been used excessively in rare cases of paroxysmal tachycardia or even paroxysmal auricular fibrillation with cessation of attacks on its omission.

Kohn⁷ in 1926 discussed the reputed epidemic of angina pectoris due to tobacco on a French warship in 1858 reported by the ship's surgeon Gelneau and demonstrated clearly that these severe pains suffered

by a number of the crew after an exhausting four-year voyage followed colic and anemia and were in all probability the result of lead poisoning rather than tobacco poisoning

Frequently writers have referred to patients who have suffered angina pectoris only during periods of smoking, with cessation of attacks on omitting tobacco. Such cases have generally been few in number when specifically mentioned, as in an article published in 1928 by Moschcowitz,⁸ who reported four cases in three men, aged 41, 52 and 61, respectively, and one woman, aged 35, in one of these four cases there was definite evidence of heart disease. Gallavardin, in nearly 800 personal observations, found only two cases of "tobacco angina" and a third in which the relationship although possible was improbable. Schlager⁹ wrote of knowing several cases of this sort, one over a period of thirty years. Now and then various physicians have told us of rare individual patients of their own, and we have encountered three such instances, one with evidence of heart disease (bundle branch block by electrocardiogram) and two without.

Nicotine poisoning in man has occasionally been reported aside from cases showing the acute toxic effects of tobacco. Nausea, vomiting, faintness, dyspnea, collapse and coma have been noted in nicotine poisoning,¹⁰ and the first mentioned of these symptoms is commonly experienced in acute tobacco poisoning, especially in young people smoking tobacco for the first time, but the heart itself has apparently not been affected so much as have the nervous system and vasomotor control. Faulkner's case of serious nicotine poisoning showed as the only cardiac abnormality ventricular premature beats, which as a matter of fact, were not surely due to the nicotine.

Alcohol and Angina Pectoris—Most writers have had little to say about the relationship of the use of alcohol to angina pectoris. It is a common opinion that the use of alcohol may help to prevent angina pectoris and that the apparent increase of angina pectoris in the United States of America during the past decade may be in part the result of prohibition. Leary¹¹ has found relatively little aortic sclerosis in alcoholic individuals. Cabot¹² in 1904 found that only 6 per cent of 283 patients with chronic and excessive alcoholism under 50 years of age showed any clinical evidence of arteriosclerosis, while only 13 per cent of 45 patients with arteriosclerosis gave any history of alcoholism and 57, or 60 per cent, of 95 patients who showed arteriosclerosis at postmortem examination were total abstainers. Gallavardin,¹³ however, stated that he had never been impressed by the influence of the prohibition of wine or alcohol in the development of the anginal syndrome, in France, where there had been no change in the alcoholic habits of the population for many years, it appeared certain that cases of angina pectoris were more numerous than before. Gallavardin believed that some other influence than the amount of alcohol used was responsible, he added that he did not

consider that alcoholism engendered the condition and, further, that "it is sufficient to see how healthy the arterial system is generally found to be in cases of cirrhosis of the liver to know that alcohol is not a poison for the arterial system."

PRESENT STUDY

A series of 750 private patients with angina pectoris examined consecutively by us over a period of twelve years from 1921 to 1933 has been analyzed to determine the amounts of tobacco and alcohol habitually used prior to the development of the angina pectoris, and this series has been compared with a control series of 750 individuals without angina pectoris and of exactly the same sex and age incidence and from the same walks of life. A group of friends has helped us in the careful collection of data of many of the individuals of the control series, and we take pleasure in expressing herewith our gratitude to these friends.

Each series that with angina pectoris and that without was composed of 566 men (75.6 per cent) and 184 women (24.4 per cent). The age distribution in

TABLE 1—Tobacco

Per cent	46.1	29.5	24.4
Control series			
Cases (total of 750)	270	220	261
Per cent	37.2	29.3	33.5

TABLE 2—Alcohol

	None	Slight to Moderate	Much to Excessive	Great Excess
Angina pectoris				
Cases (total of 750)	480	230	8	1
Per cent	64.4	31.5	1.1	
Control series				
Cases (total of 750)	463	224	63	4
Per cent	61.7	29.9	8.4	

each series was as follows: 30 to 40 years 16 patients (2.2 per cent), 40 to 50 years 106 patients (14.1 per cent), 50 to 60 years 269 patients (35.9 per cent), 60 to 70 years 271 patients (36.1 per cent), 70 to 80 years 85 patients (11.3 per cent), and 80 to 90 years 3 patients (0.4 per cent). Many of the patients with angina pectoris had complications of hypertension, valvular heart disease, coronary thrombosis and noncardiac lesions, some were uncomplicated. Most of the control subjects were healthy but some had heart lesions without angina pectoris and a few had a noncardiac disease.

The amount of tobacco used was graded as follows: 0, + (one to five cigarettes a day), ++ (five to ten cigarettes a day), +++ (ten to fifteen), ++++ (fifteen to twenty), and +++++ (over twenty). One cigar of average size was considered equivalent to four cigarettes and one pipe of average size to two cigarettes. If the tobacco smoke was not inhaled or the cigarettes, cigars or pipes only partly smoked, the amount was graded down accordingly. There was only rarely a habit of chewing tobacco in the series, this was gaged as to the number and size of the "chews" each day, the average size being graded as equivalent to a cigar.

The amount of alcohol used was graded as follows: 0, + (an infrequent drink of whisky, gin or wine, or occasional beer), ++ (two or three drinks a week), +++ (a daily drink), ++++ (more than one

daily drink), and + + + + + (heavy drinking, as for example a pint or more of whisky a day). At times it was difficult to gage the amount of alcohol accurately, as was also true of the amount of tobacco, but for the most part the data are accurate and the conclusions derived therefrom reliable.

The accompanying tables record our observations.

Other effects of tobacco and alcohol, for example in the production of premature beats or extrasystoles, were not included in our present study.

CONCLUSIONS AS TO TOBACCO AND ANGINA PECTORIS

Our observations have shown a somewhat higher percentage of total abstainers from tobacco among the patients with angina pectoris than among the individuals without angina pectoris (46.1 per cent as compared to 37.2 per cent) and a somewhat lower percentage of persons using much or an excessive amount of tobacco in the angina pectoris series than in the control series (24.4 per cent as compared to 33.5). One may simply conclude from these figures that past habits of tobacco smoking are not primarily responsible for angina pectoris. The actual balance of "better habits" in favor of the individuals who developed angina pectoris may perhaps be explained, as in the case of neurocirculatory asthenia, by their greater sensitivity to tobacco, which makes them avoid it altogether or at least in excess. Although the smoking of tobacco (especially cigarets) is largely a "nervous habit," many nervous people do not use it. Occasionally patients in our series of angina pectoris either volunteered the information or responded to questioning that omission or reduction of tobacco was helpful by causing a decrease in the frequency of attacks of angina pectoris, rarely patients ceased having attacks of angina pectoris altogether when they stopped smoking.

CONCLUSIONS AS TO ALCOHOL AND ANGINA PECTORIS

There was little difference between the two series of the cases of angina pectoris and of the control individuals with regard to the number of total abstainers from alcohol, there were 64.4 per cent in the angina pectoris series and 61.7 per cent in the control series. On the other hand, considerable or excessive use of alcohol was rare among the angina pectoris cases (eight individuals, or 1.1 per cent) but far more common among the "controls" (sixty-three individuals, or 8.4 per cent). Only one person of all the 750 patients with angina pectoris drank very heavily, while there were four such in the series without angina pectoris.¹⁴ The one case of angina pectoris just referred to proves that alcohol is not a certain prophylactic measure against angina pectoris, the patient was a man, aged 66, whose intake of strong liquor had averaged at least a quart daily for forty years or more, however, other factors, which included excessive eating, excessive physical exertion for his years and syphilis forty-six years earlier existed to counteract the beneficial effect of alcohol if such there be, the angina pectoris was of slight to moderate degree, came only on effort, and had existed for two years and four months. Among the eight other patients with angina pectoris who drank a considerable or excessive amount of strong liquor the one who drank the most (next to the record made by

the patient just referred to) survived a longer time (twenty-three and one-half years) after his first attack of angina pectoris than any one else in the series to date. Thus it may be concluded that abstention from alcohol neither protects from angina pectoris nor causes it but that the drinking of much alcohol is rarely found in the past history of patients with angina pectoris.

In the treatment of angina pectoris both for the prevention of individual attacks and for their immediate treatment, alcoholic drinks have been occasionally useful ever since they were first advised by Heberden himself more than 160 years ago. They have been largely replaced by nitrite therapy in the past sixty years, but they should not be abandoned wholly, for they frequently are still helpful and are regarded gratefully by some patients. Several of our patients with angina pectoris have referred, sometimes spontaneously, to the benefit they derived from liquor.

SUMMARY

An analysis has been made of the past habits in the use of tobacco and alcohol of 750 consecutive private patients with angina pectoris and of 750 individuals without angina pectoris of exactly the same sex and age incidence and from the same walks of life.

Comparison of these habits of the two groups shows that 46.1 per cent of the angina pectoris patients had been abstainers from tobacco while 24.4 per cent had used tobacco to excess, in contrast to 37.2 per cent of the control series who did not smoke and 33.5 per cent who smoked excessively.

Total abstinence from alcohol was the history of 64.4 per cent of the cases of angina pectoris and of 61.7 per cent of the control series. Only eight of the 750 patients with angina pectoris (1.1 per cent) drank considerable or excessive alcohol and only one of them drank very heavily, while sixty-three individuals (8.4 per cent) of the control series drank much alcohol, four of them very heavily.

It appears from this study that neither the use of nor the abstinence from tobacco or alcohol plays an important role in the genesis of angina pectoris. In occasional cases the use of tobacco apparently aggravates or precipitates attacks of angina pectoris and in occasional cases alcohol helps to prevent or to relieve such attacks.

Massachusetts General Hospital

Calcium and Phosphorus in Foods—Calcium is needed for bones, for the clotting of blood, for normal action of the heart, in the physiology of nerve conduction, and for the energy exchange of muscle contraction. It is found primarily in milk, fruits and vegetables are relatively rich, while meat and milled cereals are poor in calcium. Phosphorus is needed for the nuclear construction of every cell and is thus intimately concerned in all cell multiplication. It contributes largely to the bones and the plasma and other fluids, being found in organic union with proteins, fats and carbohydrates. It aids in the work of various glands and can be found in their products, particularly in milk and the sexual elements. It is found abundantly in eggs and milk, also in wheat (entire grain but not white flour), oatmeal, dried beans and many nuts. A growing animal can, however, fully supply its mineral requirements from inorganic sources, it is therefore unnecessary to consider the calcium, phosphorus and iron content in natural foods to the degree currently believed.—Nixon J. A. *Food Values and Their Practical Application in Dietetics*, *Brit M J* 1:1 (Jan 6) 1934.

¹⁴ Since the completion of this paper we have encountered another instance of angina pectoris in a man who has drunk to excess for fifteen years or more; this patient now 71 years old had drunk at least 1 pint of whisky a day.

NEUROLOGIC DIAGNOSIS IN TWO HUNDRED AND FIFTY CASES OF CORD BLADDER

FREDERICK C LENDRUM, MD

Fellow in Medicine the Mayo Foundation

AND

FREDERICK P MOERSCH, MD

Member of the Section on Neurology the Mayo Clinic

ROCHESTER, MINN

The term cord bladder is applied in cases in which the bladder fails to function because of lesions in the nervous system. The term neurogenic dysfunction of the bladder would be more accurate, if less picturesque. Cord bladder is used without any special reference to the site of the lesion, whether in the central or peripheral nervous system. In recent years the attempt has been made to use the term atonic bladder for the condition resulting from a lesion in the peripheral nerves and to restrict the term cord bladder to cases in which actual lesions are present in the spinal cord.¹ In 1926 Moore² investigated the sensibility of the mucosa of the bladder and stated "My findings favor the opinion that two main types of neuropathic bladder exist: (1) those resulting from some disturbance in the peripheral or local nervous mechanism and (2) those dependent on pathologic conditions of the central nervous system." The difference is not always clear cut on cystoscopic examination; however, and the distinction has not come into universal use. Learmonth,³ in observations on the physiology of the bladder, pointed out the extreme complexity of the mechanism involved. Cord bladder has received little statistical consideration since the work of Caulk and his associates⁴ in 1919.

CASES STUDIED

At the Mayo Clinic between Jan 1, 1920, and March 1, 1931, a diagnosis of cord bladder was made in 558 cases. The histories were examined, and in 250 cases the positive diagnosis of cord bladder was confirmed by cystoscopy and neurologic examination was completed. These 250 cases form the basis of this study. The patients who had both cystoscopic and neurologic examinations constitute a somewhat selected group with regard to the whole group of patients with the diagnosis of cord bladder. For example, patients with serious lesions of the spinal cord and relatively minor vesical symptoms, as in advanced multiple sclerosis, fracture of the spine or tumor of the spinal cord, were frequently not referred for cystoscopic examination. Likewise, children with lesions of the spinal cord were often not subjected to cystoscopy. Conversely, patients with but few neurologic signs or symptoms were frequently referred for cystoscopy but not for a neurologic examination. Only the neurologic observations in these 250 cases were considered, no attempt has been made to analyze the varying degrees of tribeculation, relaxation of the sphincter, failure of expulsive force or loss of vesical sensation revealed by cystoscopic examination.

Distribution by Sex—There were 221 males and 29 females in this series. This is in contrast with the almost equal sex relationship of patients of the clinic in general. Alvarez and Ascanio⁵ in 1930 noted that 12,931 male patients registered, compared to 12,412 female patients. The view is commonly expressed that the higher incidence of cord bladder among males is due to the higher incidence of syphilis among males, and to the higher incidence of tabes dorsalis among male than among female syphilitic patients. It may be noted in table 4, however, that the preponderance of male patients is almost equally great in each of the causes of cord bladder. It would appear either that the neurologic apparatus controlling the function of

between the ages of 40 and 60. In each of the major etiologic groups, however, distribution by age was distinctive. Of the patients whose cord bladder resulted from a developmental defect, 81.2 per cent came to the clinic before the age of 40, of those whose cord bladder resulted from syphilis of the central nervous system, 73.7 per cent came to the clinic between the ages of 40 and 60, and of those whose cord bladder was associated

⁵ Alvarez, W. C. and Ascanio, Hugo. The Age and Sex Distributions of Patients at the Mayo Clinic. *Human Biology* 2: 185-198 (May) 1930.

with arteriosclerosis of the central nervous system, 78.5 per cent came to the clinic after the age of 60.

Chief Complaint—The complaints with which the 250 patients came to the clinic are listed in table 2. Twenty-one patients had no complaints but came for treatment of syphilis. Thirty-six patients came because of conditions wholly unrelated to the cord bladder. The largest number of patients, 118, came because of urinary

complaints, chiefly frequency, incontinence and retention of urine. Fifty-one patients came on account of neurologic symptoms, those symptoms due to tabes dorsalis were the most common. Six patients complained of constipation, this may have been an unrelated condition or due to loss of sensation from the rectum. Similarly, the lassitude and weakness of which eleven patients complained may have been irrelevant or a consequence of the vesical condition or a result of tabes dorsalis. The duration of symptoms before the cord bladder was diagnosed may be noted in table 3. As a result of experience with cases of absolute paraplegia associated with compression myelitis, the view has grown that cord bladder is ordinarily fatal in a few years. It is apparent, however, that the gradual and usually incomplete loss of control of vesical sphincters that was observed in most of our cases is not incompatible with a long life.

Neurologic Diagnosis—The neurologic diagnosis in these 250 cases is recorded in table 4. When the neurologic examination was equivocal, the diagnosis which the consultant deemed most probable is the one that has been entered in the table. By far the most conspicuous etiologic agent was syphilis of the central nervous system, which accounted for 42.5 per cent of the cases in our series. The next most important etiologic factor, namely myelodysplasia (developmental defect) of the spinal cord, will be considered later. In 33 cases (13.2 per cent) the neurologic data were negative, and no cause for the cord bladder could be discovered. In 39 of the 250 cases a second neurologic examination was made a year or more after the first. In 34 cases the original diagnosis was confirmed and in 5 it was changed. In these 5 the final diagnosis is the one that appears in the table.

In one case a diagnosis of tabes dorsalis was changed to inflammatory myelitis at a later examination. In another case the earlier diagnosis of combined sclerosis was changed to multiple sclerosis. In the third case a

diagnosis of multiple sclerosis was changed to lateral sclerosis. In two cases in which the first neurologic examination gave entirely negative results, the patients returned later with symptoms from which the diagnosis of myelodysplasia was made.

Myelodysplasia (Developmental Defect) of the Spinal Cord—The complete picture of cord bladder resulting from myelodysplasia may be described as follows: (1) spina bifida with or without hypertrichosis over the sacrum, a deep posterior anal dimple, or other visible deformity, (2) congenital deformities of the feet or genito-urinary organs, and other congenital abnormalities, including mental defect, (3) enuresis in childhood, (4) progressive loss of urinary function in early adult life, (5) loss of sexual function, (6) loss of rectal control, (7) diminished sensation in the anal and coccygeal region, (8) atrophy of the muscles of the legs, and (9) frequently abnormalities of the reflexes.

This complete picture is rarely found. In fifty-two cases, however, the evidence was sufficient to indicate that the patients belonged in this group. In the original neurologic examination the condition was variously expressed as developmental defect of spinal cord, abiotrophia, myelodysplasia, cord bladder associated with spina bifida, primary cord bladder, or even central nervous system essentially negative. When reviewing these cases, however, the consultant was convinced that they all belonged to this single group (table 5). The diagnostic significance of spina bifida, enuresis in childhood, and early onset of urinary symptoms is apparent.

In twenty-one cases spina bifida was regarded as roentgenographically typical, and in four cases as incomplete or anomalous. In eighteen cases spina bifida was reported following roentgenograms of the kidney, ureter and bladder made as a routine. In seven cases it was noted when the films were reviewed in the light of the cystoscopic observation of cord bladder. The incidence of 48.07 per cent of spina bifida in these

cases contrasts with an incidence of 5.16 per cent found by Sutherland in 12,000 roentgenograms of the spinal column made at the Mayo Clinic⁶ and an incidence of 2.8 per cent which he noted in 1,000 roentgenograms of the urinary tract.⁷

The tendency for symptoms to progress in cases of developmental defects of the spinal cord has been

pointed out by Woltman⁸. Four of the patients in this group were given second neurologic examinations a year or more after the first examination. The symptoms in three of the patients had definitely progressed, one patient examined a year after the first examination showed no change.

This syndrome of loss of control of the vesical sphincters and of function of the sacral cord associated with spina bifida has been described by numerous observers. Woltman, Chute⁹ and Braasch¹⁰ have pointed out that the same process may occur in the spinal cord without any change that is demonstrable by roentgenograms.

CONCLUSIONS

1 Cord bladder is preponderantly a disease affecting males.

2 In each of the major etiologic groups of cord bladder, age distribution was distinctive.

3 Almost half of the patients come for treatment because of urinary symptoms (47.2 per cent) and almost

half of the remainder come because of neurologic symptoms (20.4 per cent).

4 The history of urinary symptoms frequently extends over many years, and the condition is apparently not incompatible with a long life.

5 The chief cause of cord bladder is syphilis of the central nervous system (42.4 per cent), myelodysplasia (developmental defect) of the spinal cord is the second chief cause (20.8 per cent). In 13.2 per cent of patients, no cause of the cord bladder could be found.

6 Myelodysplasia of the spinal cord resulting in cord bladder is a specific entity. Spina bifida occulta and associated congenital deformities, enuresis in childhood, early onset of symptoms of cord bladder, and loss of other functions of the sacral cord are the characteristic features of this condition.

7 Careful urologic and neurologic study of patients with disturbances of vesical function is highly important.

DIABETES INSIPIDUS

TREATMENT BY INTRANASAL INSUFFLATION OF POSTERIOR LOBE PITUITARY POWDER

FRANCIS M SMITH, MD

LA JOLLA, CALIF

No fundamental change in the symptomatic treatment of diabetes insipidus has occurred since 1913, when von der Velden¹ in Germany and Farini and Ceccaroni² in Italy, working independently, discovered the prompt, almost specific though temporary, control of excessive thirst and polyuria in patients suffering from diabetes insipidus following subcutaneous injections of extracts from the posterior lobe of the pituitary gland. Although the rôle of the posterior lobe in regulating normal water metabolism is still obscure, its antidiuretic effect with the adjustment of water balance and the correction of dehydration in diabetes insipidus has been abundantly confirmed.³

In seeking to remove the necessity for daily, painful hypodermic injections, attempts have been made to obtain the specific effect of the posterior lobe by the enteral administration of extracts⁴ and of fresh glands⁵. All have proved totally ineffective or so variable in their action as to be impracticable.

A distinct improvement in the clinical management of diabetes insipidus was made in 1922 when Blumgart⁶ demonstrated complete relief of excess thirst and polyuria by the intranasal application of pituitary extract in the form of a spray or swab as by subcutaneous injection. The technical procedures involved were thereby considerably simplified and the subjective discomforts incident to frequent hypodermic injections and the not infrequent unpleasant gastro-intestinal and circulatory side effects of the extract eliminated.⁷

The object of this comparative study is to show that successful symptomatic treatment of diabetes insipidus can be obtained in a still easier and distinctly less expensive manner by the nasal insufflation of a dry powdered posterior pituitary preparation.

Curiously enough, no comprehensive study of this form of therapy has yet appeared in the American literature, although several such reports have been published on the continent. The first report was that of Andre and Lucie Choay.⁸ A polyuria of from 15 to 18 liters was reduced to from 1,800 to 2,000 cc by snuffing three times daily 50 mg of a dry powder of posterior lobe. Each dose lasted from six to eight hours. Subsequent studies⁹ of twelve cases followed for over five years showed this treatment to be as enduring and as effective as hypodermic injections.

The powder represented a 5 X concentration of the fresh gland and was snuffed either from the "tabatiere anatomique" or from the finger tip. In five patients with urine volumes of from 15 to 20 liters, from 0.15 to 0.2 Gm of powder divided into three to six doses taken at intervals during the twenty-four hours reduced urine volumes to from 2 to 3 liters. Each dose lasted from five to ten hours during the night and from three to seven hours during the day. In five other cases urine volumes of from 8 to 12 liters were reduced to from 1,500 to 2,000 cc by a similar dosage, the effect lasting on an average to six hours during the day and from eight to ten hours at night.

Lesne and his associates¹⁰ reported the case of a child aged 11 years, suffering from diabetes insipidus due to encephalitis, in whom pituitary extract by hypodermic and nasal instillation was without effect in reducing a polyuria of from 5 to 8 liters. Two hundred milligrams of powdered posterior pituitary lobe was then given intranasally in divided doses. Two doses were without notable effect on the twenty-four hour urine volume, five reduced the volume to from 1 to 4 liters, but six doses effected a steady antidiuresis, with urine volumes of from 1 to 1.5 liters and a gain of 4 pounds (1.8 Kg) in weight. Omission of the powder allowed rapid recurrence of a polyuria, which was promptly controlled by resumption of 200 mg of powder divided into six doses.

Powdered posterior lobe and pituitary extract deposited on milk sugar to form a powder were among the various pituitary preparations tested by Rosenberg¹¹ in four cases of diabetes insipidus. He concluded that the best method of treatment was pernasal administration of extracts from the posterior lobe in the form of powder. Nothmann¹² and Calderon and Mazzei¹³ have reported similar results. Vidgoff's¹⁴ patient had the unique experience of obtaining symptomatic relief while assisting in pulverizing dry posterior lobe material. Powder treatment was started by using from 5 to 10 mg intranasally every eight to ten hours. The urine volume was reduced from 10 liters to 1,500 cc in twenty-four hours and the specific gravity was raised from 1.002 to 1.018. The symptomatic relief was prompt and complete.

METHODS

To facilitate an accurate clinical comparison of the different pituitary preparations, various disturbing factors were either eliminated or controlled in the two cases studied. The patients were hospitalized but allowed to be out of bed part of the day. The diet was repetitive, varying in selection, but throughout the test periods was of constant water, salt, protein and energy content. Patient 1 took 2,730 calories consisting of 90 Gm of protein, 130 Gm of fat, 300 Gm of carbohydrate and 2.15 Gm of sodium chloride. Patient 2 received 1,688 calories protein, 70 Gm, fat, 84 Gm, carbohydrate, 163 Gm, and sodium chloride, 1.84 Gm. All the food was completely consumed. The patients were urged to drink as much water as desired. Tea and coffee were omitted. The total volume of fluid intake consisted of all fluids as such plus the calculated water content of the food. The urine was collected in twenty-four hour periods and its volume, specific gravity and

chloride content were determined. To minimize daily variations, each therapeutic procedure was observed over a period of four consecutive days.

The powdered posterior lobe preparation,¹⁵ physically of dustlike fineness, with a slight tendency to become hygroscopic, was administered by nasal insufflation, a powder blower of small volume being used. The chosen amount was placed in the chamber, and the atomizer nozzle introduced well into the nostril and so directed that its tip pointed upward between the eyes. A few puffs deposited part of the powder on the mucous membrane, the anterior portion of the nasopharyngeal roof being covered. The remainder of the powder was then blown into the opposite nostril. Too vigorous blowing was avoided, as it scattered the powder to nonabsorbing areas of the mucous membrane. Both patients experienced a slight stinging sensation "between the eyes" when the powder was correctly placed and they soon became very expert in its application. Continued use for over a year has produced no local irritation.

OBSERVATIONS

CASE 1—Robert B., a school boy, aged 18, seen, July 17, 1932, complained of severe thirst, polyuria and fatigue. The onset in March, 1932, was insidious with nocturia as the first symptom. Several days later, thirst and polyuria appeared. All symptoms so increased in severity that by May from 8 to

Chart 1 (case 1).—Comparative effects on water balance and specific gravity of urine of voluntary fluid restriction, hypodermic injections of double strength solution of pituitary in varying doses and nasal insufflation of powdered posterior lobe. Observation periods consist of four consecutive days. The black and stippled column represents total fluid intake, white column urine output every twenty-four hours. The specific gravity of the urine is indicated by the small circles.

10 quarts of water was drunk and an equal volume of "water-like" urine passed. Fatigue appeared, the appetite was lost, rest and sleep became impossible, the weight decreased from 145 to 132 pounds (from 66 to 60 Kg), sweating ceased, the bowels became constipated, and the mouth became extremely dry. Medical assistance was sought, May 22, a diagnosis of diabetes insipidus was made, and 0.5 cc of double strength solution of pituitary twice daily by hypodermic was prescribed, with prompt relief of all symptoms. A gradual gain in weight and recovery of physical strength followed.

The past and family histories revealed no suggestive etiology other than a light case of measles one year before, and a gain of 6 inches (15 cm) in height during the past two years.

Complete physical and neurologic examinations, including perimetry, showed no abnormalities other than a distinct adolescent appearance, moderate underweight for the height (height 71½ inches [185.6 cm] and weight 124 pounds [56.2 Kg]), dry skin, and an acrocyanosis with moist, cold palms.

Stereoscopic roentgenograms of the skull showed no evidence of cranial or intracranial abnormalities.

There was no anemia. The blood serology was negative. The spinal fluid was not examined. The urine was colorless, with a specific gravity of from 1.001 to 1.004, the volume without treatment was from 8 to 10 liters every twenty-four hours,

15 A commercial powdered posterior preparation purchased in one eighth ounce (4 Gm) bottle. It represents a 5 X concentration of the wet gland.

there was a neutral reaction and it was free from albumin and sugar.

A diagnosis of diabetes insipidus of undetermined etiology was made after sterile hypodermic injections and the insufflation of an inert powder failed to influence the polydipsia and polyuria. Chart 1 shows the comparative results in this patient.

Without specific treatment the total fluid intake and output were high. The urine varied from 8,000 to 9,500 cc in twenty-four hours but was sufficiently less than the total fluid intake to allow a gain of 2 pounds (900 Gm) during the four-day test period. With great subjective discomfort the total fluids

Chart 2 (case 2) — Comparative effects on water balance and specific gravity of urine of varying doses of double strength solution of pituitary hypodermically and posterior lobe powder by nasal insufflation. Each experimental period while not sequential consisted of from two to four consecutive days. The black and stippled column represents total fluid intake, the white column urine output for twenty-four hours. The specific gravity of the urine is indicated by the small circles.

were voluntarily restricted to about two thirds of the former intake. A corresponding decrease in urine volume followed. The specific gravity of the urine was very slightly increased, but in both instances it ranged from 1001 to 1004.

In order to determine the efficiency of the proposed treatment with powdered posterior lobe, the well known effect of solution of pituitary¹⁰ by hypodermic injections was recorded. The action of increasing doses served as an excellent measure of antidiuresis and symptomatic relief. With 0.5 cc every twelve hours, urine volumes were moderately reduced but variable—from 2.5 to 5 liters. With this dose doubled, urine volumes varied but slightly and decreased to 2,000 to 2,800 cc. One cubic centimeter of solution of pituitary hypodermically every eight hours lowered the urine output to from 1,200 to 1,880 cc. A proportionate decrease in total fluid intake and a progressive increase in water balance with a gain in weight was effected. The urine became increasingly concentrated, as shown by the rising specific gravity, the appearance of normal urine pigmentation and the increased chloride concentration. All subjective complaints were characteristically and promptly relieved.

When 40 mg of the powdered pituitary substance was insufflated into the nose at eight-hour intervals, an antidiuretic effect comparable to that produced by two injections of 1 cc of solution of pituitary at twelve-hour intervals occurred. With a distinct retention of water in the body, the urine became normally concentrated with specific gravities of from 1012 to 1014, and with volumes reduced to about 2,000 cc.

Both forms of pituitary preparation allowed a daily, progressive decrease in the voluntary consumption of fluids during the four-day test period. With the powder, a very nice balance of intake and output at from 1,500 to 1,800 cc was reached on the third and fourth days.

The patient has now been under treatment for a year, using 40 mg of the powder insufflated into the nose three times a day (7 a m, 2 p m and 10 p m), and this fluid balance has been maintained.

CASE 2—Barbara S., aged 22, a musician, unmarried, had never been seriously ill, although she had been frail as a child. The family history was irrelevant. At the age of 20 a heart murmur and infected tonsils were found during a life insurance examination. The tonsils were removed and perfect health was enjoyed until Jan 30 1932, when, without apparent reason, an extreme thirst and dry feeling in the mouth suddenly

appeared. Large quantities of water were taken for two days before polyuria was noticeable. The symptoms reached a maximum in about two weeks when from 6 to 8 quarts of water was drunk and an equal amount of urine passed in twenty-four hours. Sleep was greatly disturbed, the weight decreased from 115 to 105 pounds (52 to 47.6 Kg). A diagnosis of diabetes insipidus was made six weeks after the onset. Voluntary fluid restriction reduced the urine volume to 4 or 5 quarts daily, but the thirst became unbearable. Injection of 1 cc of double strength solution of pituitary daily at noon promptly reduced all symptoms. The urine volumes averaged from 2 to 3 quarts. Severe abdominal cramps, dizziness and palpitation lasting from fifteen to twenty minutes followed each injection. The patient was much relieved otherwise.

Pertinent physical manifestations were mild undernutrition, nervousness and emotional instability. Neurologic examination, including perimetry and stereoscopic roentgenograms of the skull, was negative. The blood counts were normal. The Wassermann test was negative. The spinal fluid was not examined. The urine was colorless, with a specific gravity of from 1002 to 1005, and was negative for sugar and albumin. A series of sterile hypodermics failed to influence the symptoms, so a diagnosis of diabetes insipidus of the idiopathic type was made.

Chart 2 records the experimental results in this case.

Owing to general weakness, nervousness and rapid loss of weight, discontinuance of specific treatment for more than two days was impossible. During this time 9½ quarts of colorless urine was passed daily, a markedly negative water balance with a loss of 4 pounds (1,800 Gm) occurred. Although the patient was extremely thirsty, water provoked a nasty taste almost as disagreeable as the polydipsia.

Solution of pituitary hypodermically, 1 cc daily, promptly controlled the distressing thirst and polyuria. Several days of specific treatment were necessary before the patient could cooperate sufficiently to take the daily repetitive diet. When it was stabilized, the four-day observation recorded in chart 2 was made.

A small water balance allowed additional gains in weight. The urine volumes were reduced but varied between 2,500 and

Chart 3 (case 1) — Comparative effect of different methods of treatment with pituitary preparations on volume, specific gravity and chloride content of the urine collected at half hour intervals.

3,500 cc. A low specific gravity persisted. The injection of a second but smaller dose (0.5 cc) of solution of pituitary twelve hours after the large dose caused proportionately greater effect. Urine volumes diminished to 2,000 cc daily, the specific gravity increased to 1006, and more water was retained.

After standardization of antidiuresis had been effected at two levels of subcutaneous pituitary extract administration, the comparative effect of powdered posterior lobe was tested, as will be seen in chart 2. Intranasal insufflation of 40 mg of powder at eight-hour intervals during a four-day period caused a progressive decrease in voluntary fluid intake, and the urine

volumes diminished from 2,800 to 1,800 cc. The specific gravity reached 1.011. From these results it appears that the therapeutic effect of 40 mg of powdered posterior lobe three times a day compares favorably with 15 cc of solution of pituitary given in two injections at twelve-hour intervals. A dose of 40 mg of powder twice daily had about the same effect as 1 cc of solution once a day. Even when fluids were forced a considerable portion was retained in the body so long as a steady dosage of the powder was continued.

Chart 4 (case 2)—Comparative effects of different methods of treatment with pituitary preparations on volume, specific gravity and chloride content of urine collected at short intervals

The patient has now been observed for over a year and has maintained a normal condition by taking approximately 40 to 50 mg of the powder three times a day at eight-hour intervals. The urine varies from 1,500 to 2,500 cc daily, depending on the season, the fluid intake and the salt content of the food. Several head colds with rhinorrhea have left the therapeutic benefits unaffected. The nasal mucous membranes have not become irritated by the constant local application of the powder. Troublesome intestinal and cardiac reactions induced by injections of the solution have been uniformly absent under the new form of treatment.

A more detailed investigation of the comparative effects of the two posterior lobe preparations was made to determine the time of onset and the duration of antidiuresis. In addition to the standard conditions already indicated, a constant diuresis was provoked by the ingestion of 1,000 cc of distilled water between 9:15 and 9:30 a.m. Promptly at 9:30 a.m. the pituitary preparation to be tested was given by hypodermic needle or by nasal insufflation. The urine was collected at from half hourly to hourly intervals for twelve hours, beginning at 7:30 a.m. and its volume, specific gravity and chloride concentration were determined. The results are shown in the accompanying table and in charts 3 and 4.

In both patients the absence of specific medication allowed a rapidly increasing diuresis to be added to that already present because of diabetes insipidus. Reaching its maximum from one to two hours after water ingestion, it remained high, although variable throughout the day, to drop sharply after eight or nine hours. The chloride concentrations were for the most part below 0.10 per cent, and specific gravities ranged from 1.001 to 1.004. The reactions following the injection of 0.5 cc of double strength solution of pituitary were also very similar in the two cases. The urine volumes dropped precipitously, reaching a uniformly low volume within one hour, at which they remained for from eight to ten hours and then rapidly increased. The specific gravities increased to a maximum of about

1.021 in four hours. The chloride concentrations closely followed changes in the volume of urine but began to decline before the antidiuretic effect of solution of pituitary had lessened.

Only quantitative differences in the results cited appeared when specific medication was applied in powder form. As shown in charts 3 and 4 and in the table, a single dose of 40 mg reduced the urine volume, and increased the specific gravity and chloride concentration as promptly as did the injection of the solution. The duration of effect (case 1) was shorter, lasting about five hours. Two doses of powder in case 2 produced a prolonged antidiuresis, and the specific gravity and chloride concentrations were the highest observed in any experiment. Gutmann¹⁷ has shown that exactly the same changes in water economy are produced when solution of pituitary is injected into normal persons.

That ingestion of sodium chloride increases diuresis is well known. It seemed of considerable practical importance to determine its influence on the therapeutic effects of postpituitary medication in diabetes insipidus. Chart 4 shows the effects of ingestion of 1,000 cc of 0.10 saline solution in place of the distilled water used in the other comparative tests. The urine volume was doubled and the total effective period shortened. A distinct thirst appeared and the patient's spontaneous fluid intake was 1,000 cc more than in the other experimental periods. Evidently pituitary therapy is specific only in controlling water diuresis. This corresponds to the observations of Adolph and Erickson¹⁸ in normal men. Tallquist¹⁹ recognized the benefit of salt restriction in the management of diabetes insipidus thirty years ago. Urine volumes were reduced 50 per cent or more in three cases studied by Allen and

The treatment of diabetes insipidus in common with other diseases requiring prolonged substitution therapy with a glandular product presents a distinct economic problem in many cases

Judging from the experience of the two cases here reported, the powder form of treatment reduced the daily cost about 80 per cent. The retail price of solution of pituitary varies from about 45 cents to 65 cents for a 1 cc ampule, according to the form used.

Powdered posterior lobe costs from \$3.75 to \$4 for 4 Gm, or about 5 cents for a 50 mg dose.

SUMMARY AND CONCLUSIONS

1 Two cases of diabetes insipidus of undetermined etiology were studied under standard conditions to determine the relative effects of the usual treatment by subcutaneous injections of solution of pituitary and a modified treatment by intranasal insufflation of a powdered posterior lobe preparation.

2 Intranasal insufflation of the powder in doses of from 40 to 50 mg three times a day was shown to be as effective in maintaining a normal water balance with attendant alleviation of all symptoms as from 15 to 2 cc of double strength solution of pituitary, administered subcutaneously.

3 Advantages of the powder treatment include ease of application, absence of intestinal, cardiovascular or other side effects, and most of all a reduction in cost to less than one-fifth that of solution of pituitary.

4 A moderate dietary salt restriction is beneficial in the management of diabetes insipidus.

ASTHMA IN CHILDREN

ITS CAUSES AND TREATMENT

ROBERT A. COOKE, M.D.

NEW YORK

The incidence of asthma, whether in children or in adults, has never been accurately determined but has been roughly estimated at 2.5 per thousand of population. Its importance lies not in its great frequency and certainly not in its mortality but essentially in the fact that in those afflicted with it the morbidity is very high; hence in infants and children it assumes economic importance because of professional care during the attack and the loss of time at home from nursing. For the child, it is important because of the interference with nutrition, education and recreation.

The knowledge of asthma has advanced in the last fifteen to twenty years with the development of allergy.

Asthma is defined as a condition of dyspnea caused by an allergic reaction involving the bronchi and bronchioles. This, of course, excludes all such causes of dyspnea as pleural, pulmonary, cardiac and mediastinal disease, chemical alterations of the blood causing dyspnea, and bronchial stenosis from tumors and foreign bodies.

In defining asthma as an allergic reaction it is necessary, then, to define allergy and to explain briefly the present conceptions of it, for, as will be seen, there are several different forms and many different specific causes.¹

An allergic reaction is one that is qualitatively altered from the normal of the species and is specific. This purposely does not indicate whether the allergic state is artificially induced by contact with the specific cause or whether it develops spontaneously without known contact. But this at once furnishes the thought for a basis of differentiation. There are allergic states that are readily induced by proper contact with foreign substances, as, for example, in man or animal by the injection of foreign serum or after infection with tubercle, and in man after contact with oil of poison ivy. I have coined the term "physiologic allergy" to designate those forms of specifically altered reactivity because they are the normal response of the majority of the species under proper conditions of contact. The tuberculin reaction is a normal and therefore physiologic response to tubercle infection. About 90 per cent of human beings injected with sufficient horse serum will have serum disease, which is an allergy, and thereafter for some time they will show a positive skin reaction to horse serum.

But the allergic reactions to tuberculin and to horse serum are not identical. The former is a delayed inflammatory reaction, while the latter is an immediate edematous one; hence clinically and histologically and immunologically these allergies have important differences and yet they are allergies according to the definition given.

Of more importance to the physician, however, are those clinical allergies which apparently develop spontaneously in but a limited percentage of the human race and as clinical entities have never been artificially induced by contact. I refer to such conditions as asthma, hay fever, eczema, urticaria and the varied manifestations of angioneurotic edema. In contrast with the physiologic they may be grouped as spontaneous or pathologic or hereditary allergies and the reason for the latter appellation is that in all these clinical allergies there is an extraordinary degree of familial occurrence.

And yet these hereditary allergies may have histologic, immunologic and clinical differences. They may be divided into two types: the immediate and the delayed.

CLASSIFICATION OF ALLERGIES

Immediate Allergies—If a child has asthma on contact with a horse or with pollen, it will be noted that the attack develops almost immediately on contact, that is, within one hour. When skin tested with the proper extract of horse dander or pollen, the positive wheal appears within a very few minutes. In the serum of such cases the specific sensitizing antibodies can be demonstrated by the method of passive transfer of Prausnitz and Kustner. The immediate clinical response can be verified by the immediate skin test, and with reservations the immediate skin test can be verified by an immediate clinical reaction, never a delayed one.

Delayed Allergies—In contrast with this there are reactions that begin not immediately but in from two hours to two or even three days after contact with the exciting cause. These are called the "delayed reactions," and this distinction is important because, in them, skin tests with the specific substance are quite uniformly negative, and immune bodies are not demonstrable in the serum. In this group occur most of the cases of urticaria, angioneurotic edema, eczema and infective asthma and a few cases of asthma due to foods and to air-borne substances. These delayed

allergies account for the unsatisfactory results of tests in cases that happen to fall in this group. A brief synopsis of such a case will illustrate this point.

A boy, aged 4½ years, seen in July, 1931, had been asthmatic over two years. Originally the attacks were paroxysmal and afebrile, but they had been continuous for the past six months. There were no gastro-intestinal symptoms. By intradermal test, positive reactions were obtained to house dust and to

horse and dog danders. Tests with all foods, including milk, were negative. Under proper environmental conditions the attack continued. After milk was avoided, the attacks ceased. August 11 at 6 p. m. he was given a supper of bread and milk. At 8 o'clock he began to be asthmatic and at 9 the attack was severe and continued all night. There was a noticeable edema of the face the following morning. During the day the attack disappeared. On a milk-free diet and with environmental care he has been free to date.

The important points to bear in mind, then, regarding the clinical types of allergy and their relation to skin tests are these:

1. The so-called positive skin test to foods and air-borne substances is an immediate reaction and can occur only in those cases in which the clinical reaction is immediate.

2. The skin test is negative if the clinical allergy is of the delayed type, hence a negative skin test does not exclude the possibility of allergy to the test substance.

3. Delayed skin tests to foods and air-borne substances have no known clinical significance.

ETIOLOGIC FACTORS IN ASTHMA

Predisposing Cause of Asthma—It has been shown and is now generally accepted that heredity is the important predisposing cause of asthma as well as the other allergies.² This is well shown in the figures of table 1.³ The antecedent history of allergy is positive in 110, or 67.5 per cent, of 163 cases of asthma of the skin-sensitive (immediate) type with asthma beginning before the age of 15, and is positive in 73 per cent of 66 cases of infective asthma (delayed type) in the same age group. This is evidence that these two types, the immediate and the delayed, have a common background of inheritance. Further, the age of onset of the allergy is influenced by the degree or amount of

inheritance,⁴ as shown by the fact that with bilateral inheritance 75 per cent of the offspring will be affected and in 66 per cent of these the onset will take place before the tenth year. When inheritance is unilateral, about 50 per cent of the offspring will develop allergy and in 31 per cent of these the onset will occur before the tenth year. But neither the specific sensitization nor its clinical form is inherited, only the capacity for or tendency to it.

Cause of Sensitization—Proper inquiry is then in order as to, first, the cause of the development of the sensitization mechanism and, second, the factors determining the particular allergen in a given case. As to the former, stimulation by contact is suggested on the basis of knowledge of artificial sensitization, and support to the view is given by the fact that nearly 65 per cent of the reactions in infants are caused by foods, contact being possible in intra-uterine life, but the proof that contact is necessary is not yet entirely complete. As to the second point, the factors determining the allergen, there is no definite knowledge. Excessive contact is not a requisite. Assuming that contact is necessary, one must also assume that the allergen is predetermined for the organism by nature or inheritance, for other contacts great and small will not be effective.

Cause of Asthmatic Dyspnea—The free entrance and exit of air through the bronchi is impeded. The lumen may be narrowed by increased thickness of the wall, by muscular contraction or by plugging with exudate. The theory of bronchospasm is an old one. Theoretically it is possible, and actual hypertrophy of

this layer has been shown, notably in the paper of Huber and Koessler,⁵ but a survey of their work shows that the muscular hypertrophy is not as great in asthma as it is in chronic bronchitis. This is well shown in table 2, which was made from their figures but has been rearranged for comparison. It is necessary only to point out that, in the twelve sets of comparative measurements of bronchi from 0.5 to 120 mm in

diameter, the wall is thicker five times in the asthmatic cases and six times in the chronic bronchitis cases. As for the epithelial layer, there is no comparison. The subepithelial layer is wider five times in asthmas and five times in bronchitis. The muscular layer, however, is thicker twice in asthma and nine times in chronic bronchitis. This is to be contrasted with the fact that the glandular layer is greater six times in asthma, all in the smaller bronchi, while it is greater three times in bronchitis, all these, however, are in the larger bronchi from 9 to 12 mm. These facts seem very significant.

Further, there is no mechanism for muscular contraction such as occurs in the anaphylactic animal.⁶ The smooth muscle sensitizing antibodies have never been demonstrated by animal experiment to exist in asthmatic man, though they are present in man artificially sensitized by injection of horse serum. This leaves only the hypothesis that the bronchial muscle may be stimulated to contract through the reflex action of the autonomic nervous system. That some such action takes place may be assumed in order to account for the hypertrophy, but it can hardly be believed that it is the principal factor in dyspnea since the hypertrophy is less than in chronic bronchitis in which dyspnea is not a feature.

40-50	12	2	12
Over 50	5	2	5

Edema of the bronchial wall is entirely in conformity with what is seen of the allergic reaction in hay fever, which is so frequently associated with asthma and in the allergic test reaction of the skin, as well as in pathologic sections of bronchi of asthmatic patients. Bronchial plugging with the tough viscid exudate must also be regarded as an important factor in bronchial obstruction. Clinical experience with epinephrine in relieving asthmatic dyspnea indicates that its main effect on the bronchi is obtained by its stimulation of the capillaries of the mucous membrane, and edema disappears just as it is seen to do in the nasal membranes similarly affected and in urticaria. As a result of this tissue shrinkage, the mucoid plugs are loosened and may be expelled by coughing, and air again freely enters the pulmonary alveoli. I believe that this explanation of the epinephrine action in asthma is more satisfactory than that the drug has any action to relax contracted smooth muscle fiber of the smaller bronchi.

Specific Causes of Asthma—The substances acting as exciting causes of the asthmatic attack may be inhaled from the air, ingested as foods and drugs, injected subcutaneously or absorbed from foci of infection. Inhaled, ingested and injected substances are the important factors in what have been called the "immediate" reaction and therefore they usually give the immediate positive skin test in proper cases.

Rarely, foods and inhalants do act to produce the delayed reaction of asthma and in such cases skin tests are negative, as in the case cited. Infection is the chief cause of the delayed reaction. So far as is known, it always acts in this way.

The causes of asthma have been determined in a specially studied group of 260 cases (table 3), in which all of the cases were of the immediate type and therefore skin sensitive, and in all cases the foods and inhalants actually caused asthma. They were not merely called causes on the basis of positive skin tests.

In the first age group, up to 3 years, the twenty-seven patients were sensitive either to foods or to inhalants, never to both. In the next age group, from 3 to 5 years, only two of the ten patients who were sensitive to food were sensitive to foods alone, and thereafter all the patients sensitive to food were also sensitive to air-borne substances with one exception (in the 20-30 year group).

This table illustrates very well the importance of the foods in the early years of life and the relative unimportance after the tenth year, indeed almost after the fifth year. On the contrary, the air-borne substances come to the fore after the fifth year and begin in the third year, but rarely sooner.

The principal air-borne substances rank as follows in the ninety-four cases (up to 15 years of age): house dust, 55 cases, ragweed, 21 cases, feather, 19 cases, animal epithelia, 12 cases, grass pollen, 6 cases, orris root, 5 cases, cottonseed, 1 case, and kapok, 1 case.

There are 118 causes for the 94 cases, as in many cases reactions occur to several substances. In the forty-five patients under 15 years of age who are sensitive to food, only twelve have single reactions. The rest vary from two to six. The list with the number of reactions is as follows: egg white, 13 cases, chicken, 8 cases, cereal, 12 cases, milk, 10 cases, fish, 10 cases, beef, 8 cases, nuts, 7 cases, cinnamon, 1 case, pea, 4 cases, spinach, 1 case, shad roe, 1 case, celery, 1 case, cauliflower, 1 case, potato, 2 cases, chocolate, 1 case, mustard, 2 cases, orange, 1 case.

The striking peculiarity of the food allergy of infancy is its tendency to spontaneous disappearance by or before the age of 10. My impression is that this occurs in about nine out of ten cases. Occasionally food sensitizations develop in later life, hence the fact that they are found in adults does not necessarily indicate the continuance of an allergy of infancy. Unfortunately, however, this loss of early food sensitization does not end the difficulties of these children, for about 50 per cent acquire clinical allergy to air-borne substances by the age of 10 years and another 25 per cent by the age of 25. This indicates strikingly what is meant by the allergic constitution.

Cause of Infective Asthma—In practically all these cases the infection begins in the upper respiratory tract. In many cases there is a history of a previous acute respiratory infection such as whooping cough, measles or pneumonia, followed after several months by recurring bronchitis, which finally assumes a definite asthmatic character. It is my belief, not susceptible of actual proof, that such diseases have left behind foci of infection from secondary invaders, which in their turn become primary causes of the asthmatic allergy. Up to the age of 5 these foci are located in the lymphoid tissue of tonsils, pharynx and nasopharynx. After this, and with the development of the paranasal sinuses, infection not infrequently becomes localized also in these cavities. The organisms most

frequently responsible are *Pneumococcus*, *Streptococcus haemolyticus*, *Staphylococcus* both hemolytic and non-hemolytic, *Micrococcus catenulalis* and *Streptococcus viridans*.

COMPARISON OF SENSITIVE AND INFECTIVE GROUPS

It is interesting and instructive to compare the relative frequency of the two forms of asthma and for this purpose a chart has been prepared from table 1 the combined group being omitted. It shows that infection, while certainly not negligible in the early years is relatively less important but becomes much more important with age and especially so in asthma beginning after the patient is 30.

NONSPECIFIC CAUSES

Much emphasis is laid by patients on the group of apparent causes of asthma such as exercise eating heat humidity and extreme cold. It is true that in the asthmatic many or all of these do excite an attack, but as far as I can see they are not fundamental causes. The bronchial tissues rendered unstable by long continued specific reactions do respond to many irritations. The best proof of their nonspecific action lies in the fact that asthmatic patients freed of attacks for a reasonable period no longer respond to this form of irritation. The same cannot be said for the action of certain gases, such as sulphur dioxide and incense fumes. There is no proof as yet of the specificity of action of these irritants but there is clinical ground for believing it may exist because these fumes and gases precipitate the attack in relatively few asthmatic patients and may do so even after long periods of freedom from asthma. Recently a patient who had been practically free from asthma for nearly a year had a severe attack lasting three days almost immediately on entering a room in which incense was burning.

THE TREATMENT OF ASTHMA

The Acute Attack—Epinephrine in sufficient amounts by hypodermic injection and repeated if necessary at frequent intervals is the drug on which chief reliance is placed to combat the acute attack. When the attack is severe and continued, codeine or morphine may be required. The oxygen chamber or oxygen by nasal catheter is very useful especially when cyanosis exists. Inhalation of stramonium powders or benzoinated steam may also help. Mustard or flaxseed poultices may be applied to the chest but only in those children known not to be sensitive to these substances. Expectant drugs such as ammonium chloride and iodide seem to accomplish very little, but ipecac in doses to produce vomiting may be very useful. I have never seen any benefit from atropine, benzyl benzoate or glyceryl trimurate. Ephedrine alone or with amylal is useful in the milder attacks when the dyspnea is a discomfort and does not represent a vital struggle for air. The diet must be very light. The bowels should be kept freely open with catharsis or an enema. The room should be warm but the air fresh.

In those cases in which the acute attack is associated with an infection of the upper respiratory tract a local cleansing nasal douche may be beneficial as is also the occasional intral irrigation in older children, but the use of irritant antiseptics and mild silver protein packs have not been efficacious.

Management of the Asthmatic Child—But more important is the treatment directed toward the cause of the asthmatic state. Accurate and complete diag-

nosis of all the causes is the prerequisite of successful treatment, which also depends on a knowledge of the habits the diet and the physical state of the patient. It is not within the sphere of my topic here to discuss the details of diagnosis. Much has been written and much might be said about the uses the interpretations and the vagaries of the skin tests. A proper conception of them is that they are important aids when used with proper care, but they constitute only one phase of a complete diagnostic study.

In the management of these cases it must be remembered that not a particular disease entity is being dealt with but rather a condition which is the expression of the inherited allergic constitution, which usually remains through life. "Once an allergic always an allergic" contains more than a gram of truth, so that these cases are not problems of the moment but should be supervised and examined for developing tendencies at regular but infrequent intervals. Good and lasting results are not to be obtained in a short time. Hence those who are specially working in this field of medicine can succeed only with the full cooperation of the family physician. The object of treatment is to reduce to nil the clinical manifestations of existing allergy and to prevent the development of conditions favoring new allergies. The constitutional background cannot be changed. The former I seek to obtain by treatment.

Curve showing age of onset of sensitive as against infective asthma group

directed against the specific cause the latter will be outlined under preventive measures.

General measures to promote growth and improved physical condition are of course important. Fatigue should be avoided. Attention must be paid to nutrition but asthmatic children do better when not overfed. The evening meal should be light. Vitamin A preparations of animal or vegetable origin have a certain scientific basis in raising resistance to infection and are useful especially in children subject to the so-called winter cold. On account of the frequency with which air-borne substances such as house dust and animal danders act as causes scrupulous measures for environmental cleanliness are necessary, especially with regard to mattresses and pillows. Household pets should preferably be banned for though not at the time proved factors they may at any time become so in the developing child. Iodides are not really useful and over an extended period may upset digestion.

Specific Treatment of the Skin-Sensitive Type—In children clinically sensitive to foods or air-borne substances, the simplest procedure is avoidance of the cause. In infants sensitive to foods this is most satisfactory, as they usually outgrow the sensitiveness in a few years' time, but in older children this is not so and resort must be had to injection with the specific allergens if it is an important food such as milk or eggs. These must be continued for a long period of

time My procedure is slowly to increase injections at weekly intervals up to a point of sufficient clinical tolerance The injections are then continued at monthly intervals for several years This is the principle on which I also act when the allergen is an air-borne substance such as dust, dander or pollen

Treatment of the Infective Type—Cases of asthma due to infection are managed on the same general principles Although primary asthmatic bronchitis does occur in infants, it is rare Practically all these babies show infection or hyperplasia of the lymphoid tissue of the pharynx and nasopharynx Most of the acute exacerbations are associated with a general infection of the nasal membranes A little later in life as the sinuses develop the infection spreads to them and after repeated attacks the sinuses become important primary foci This, I believe, is one reason for the poor results of tonsillectomy The operation has been deferred too long, whereas it should be done early in life Another reason is faulty operative technique It is necessary to emphasize this point on account of the frequency with which secondary tonsil operations are required In the clinic with which I am associated, over 50 per cent of the tonsil and adenoid operations are of this type Early removal of the tonsils is frequently opposed on the ground that it leads to lymphoid hyperplasia of the posterior pharyngeal wall Dr Grove and I have examined many children with this idea in mind and do not believe that this objection is valid, for hyperplasia was found as frequently in children with as in those without tonsils Our feeling is that it results from long continued infection higher up in the sinuses and adenoids This condition requires treatment when once well established, but it is not usually susceptible to surgical procedure For a number of years Dr Remei has been treating these patients for us with x-rays This treatment appears to be effective provided the infected sinuses are properly treated and any mass of adenoid is surgically removed In our clinic operative procedures on children under 15 are limited to those which have been outlined We have not found it necessary to operate on sinuses at this early age

Vaccine Therapy—The mechanism by which bacteria produce the allergic reaction of asthma is not yet known It is possible to produce asthma in certain of these cases with minute doses of vaccine of the proper organism It is known that allergy of the delayed type begins in from six to thirty-six hours after the vaccine injection Contrary to the reports of Thomas⁷ and others, the skin test with bacterial vaccines has proved of no value in our hands in determining the organism responsible for the asthma in the individual case An immediate vaccine reaction rarely occurs, and when it does it has no clinical significance A delayed skin reaction does reveal some sort of sensitization, but this may be obtained with vaccines that do not produce asthma, while a negative skin reaction frequently results with a vaccine that gives asthma This symptomatic reaction is at present the sole accurate criterion Treatment with vaccines of such capacity has to be given with extreme care I have seen a symptomatic reaction with such doses as 0.0001 cc of a 1 per cent suspension Such vaccines given carefully over long periods of time may produce beneficial results in certain cases but only in those cases in which primary foci have received appropriate treatment The effect of vaccine therapy is very hard to evaluate

It is, of course possible to produce these symptomatic asthmatic reactions with nonautogenous vaccines and in the absence of autogenous cultures it may be necessary to use them, and good results may be obtained at times It is my practice to use those autogenous vaccines which produce a symptomatic asthma and thus I secure my best results

Nonspecific Treatment—On account of the difficulties of treatment in asthma and especially in the bacterial group, many procedures have been and are being proposed in the hope of temporary or permanent relief Tuberculin typhoid vaccine, milk, calcium, peptone and polypeptides, whether by injection or by mouth, can, I believe, be dismissed as of no value

The use of vaccines for nonspecific immunity is not so easily discarded but they are certainly not superior to autogenous cultures

Measures to produce hyperpyrexia simulating an intercurrent infection⁸ such as heat or intravenous vaccine do seem to produce an effect, but it is temporary and hardly worth the dangers or the exhaustion incident to their use

Preventive Measures—From what has been said and from what is known regarding the familial occurrence of the clinical allergies I believe that certain steps are justified in the offspring of parents known to be allergic and especially if the parents have asthma There is no known way to prevent the development of a predetermined allergy of the immediate type (skin sensitive) to foods or air-borne substances Difficult cases in such families are often due to sensitizations and should be studied with this idea in mind Of considerable practical value is the fact that allergic children frequently exhibit an instinctive dislike for foods to which they are sensitive and children who are not 'finicky' but regularly refuse one or several foods while showing a rational relish for the remainder of their diet should not be forced to eat them Tests have frequently shown the correctness of their instinct

For these predisposed children, even before the development of symptoms, unusual, unnecessary and intimate animal contacts are not desirable Even though the sensitization is not prevented, the clinical expression of it can be delayed during the formative years

Of greater importance, however, are the steps that may be taken for these infants or children who early show the probability of infective asthma by repeated 'colds' Practically all these cases show lymphoid hyperplasia The early and complete removal of tonsils and adenoids is to my mind, distinctly indicated, and when house dust or other factors are contributing causes by producing nasal congestion, specific treatment is also indicated Repeated infections of the upper respiratory tract in these predisposed children are not infrequently the result of contact with parents and nursemaids who themselves have a chronic respiratory infection This exposure of susceptible children is not much more excusable than contact with tuberculosis It should be avoided

In all cases, treatment should be begun with the first indication of an asthmatic tendency A proper control of these early attacks lessens the chances of returning trouble in later life

CALCIUM AND PHOSPHORUS STUDIES

IN THE IMPORTANCE OF LOW DIETARY
PHOSPHORUS IN THE TREATMENT
OF PARATHYROID TETANY

DAVID H SHELLING, M.D.
AND

MORTON J GOODMAN, M.D.
BALTIMORE

Although the incidence of parathyroid tetany is rather small, nevertheless its treatment is sometimes attended by certain difficulties, especially when the disease assumes the chronic form and the injection of parathyroid extract and the ingestion of large doses of calcium salts become necessary. The observation of MacCallum and Voegtlin¹ that parathyroidectomy results in a lowering of the concentration of the serum calcium led to the use of calcium salts as a specific for this and other forms of tetany. Later studies by Greenwald² and others³ demonstrated that in parathyroid tetany not only is the calcium in the serum reduced but the inorganic phosphorus is elevated and retained in the organism.

The latter observations indicated that the hyperphosphatemia may be as important as the hypocalcemia in the maintenance of hyperirritability, if not more so. That the phosphorus retention may be an important factor in parathyroid tetany is also borne out by recent experiments.^{3a} It was found that when an excess of phosphorus is added to an otherwise adequate diet and fed to rats with intact parathyroids, the animals partake of fairly optimal amounts of the food and rid themselves of the excess phosphorus by excretion, mainly in the urine. After parathyroidectomy, however, these animals are unable to dispose of the excess phosphorus ingested unless an abundance of calcium is also present in the diet so that it might be excreted in the bowel as the insoluble calcium phosphate. If the food calcium is insufficient or the phosphorus intake is unduly high so that the serum inorganic phosphorus becomes elevated, the animals refuse to eat the rations. When, however, the phosphorus of the diet is diminished, the animals resume eating and lose their tetany.

Apparently, the same amount of calcium in the diet which is ineffectual in relieving tetany when the dietary phosphorus is high becomes adequate when the phosphorus intake is lowered. Thus the ingestion of an excess phosphorus along with a seemingly adequate calcium intake may induce tetany just as if a low calcium diet had been partaken. This may be due to the fact that the retained phosphorus tends to be excreted into the bowel as the insoluble salt of calcium and thus robs the body of its available calcium necessary to ward off the tetanic manifestation, and also to the fact that the solubility product constant (K_{sp}) of calcium phosphate in the blood is more or less limited so that an increase in phosphate [$PO_4^{'''}$], due to retention will result in a reciprocal decrease in calcium [Ca^{++}] and thus maintain the hypocalcemia.

For these reasons it seemed advisable that in the dietary treatment of parathyroid tetany much better results could be obtained in ameliorating the hyperirritability and the calcemia by keeping the phosphorus content of the diet at minimal levels and the calcium intake higher than that of phosphorus. Of course, the maintenance of a nontetanic serum calcium level may be accomplished by the judicious use of parathyroid extract, but the fact that its use is attended by certain difficulties such as the necessity of frequent blood chemical examinations, the danger of hypercalcemia, metastatic calcification and renal impairment makes its use unsatisfactory in the ambulatory patient. Also, as will be shown later much larger doses of the hormone are required to elevate the levels of serum calcium when the intake of phosphorus is high than when it is low.

Because of the relative infrequency of parathyroid tetany, the opportunity to test this diet under controlled conditions is therefore limited to but a few cases. However, the encouraging results obtained in the few cases and some of the chemical observations on the blood and urine prompted this preliminary report, with the hope that others might find this type of diet of value in similar cases.

REPORT OF CASES

CASE 1⁴—A Negress, aged 36, who had had exophthalmic goiter for about three years, underwent a partial double thyroidectomy in September, 1931. Two weeks after operation she had epigastric distress, stiffness and cramps in her hands and feet. On admission to the hospital she was found to have hypertension (160 systolic, 110 diastolic), typical pedal spasm, positive Chvostek and Trousseau signs and a positive Trousseau test in less than a minute. The serum calcium and inorganic phosphorus were 55 and 52 mg per hundred cubic centimeters, respectively. She was placed on a weighed diet with added calcium lactate so that she consumed about 10 Gm of phosphorus and 20 Gm of calcium daily. But, in spite of the added calcium to the diet, the serum calcium rose but little, the phosphorus remained at high levels and the symptoms of tetany persisted. Because of the slow progress, the diet was changed on the sixteenth day after admission. She was given a diet in which the calcium remained at about 20 Gm but the phosphorus was reduced to about 0.270 Gm daily. On this regimen the serum inorganic phosphorus fell and the stiffness and tingling sensation disappeared, although the serum calcium rose but moderately. On the twenty-third day of the low phosphorus period, twenty-four hour specimens of urine were begun to be collected and the daily urinary excretion of calcium and of phosphorus were determined. It is interesting that the urine obtained during the low phosphorus regimen contained little or no phosphorus as shown in the accompanying chart indicating that the low serum inorganic phosphorus was brought about by (1) the low phosphorus intake and (2), possibly, by the excretion in the feces as the insoluble calcium phosphate, rather than by loss through the kidney.

Since the advent of viosterol as an antirachitic and antispasmodic in the rickets and tetany of infants, its use has also been extended by some⁵ to parathyroid tetany. Although it is well established that vitamin D will elevate the serum calcium from tetanic to optimal levels, yet its use in parathyroid tetany is not without danger, as pointed out previously⁶ namely, increased phosphorus retention and possible metastatic calcification. In order to prove this point further, the patient was given 4 cc of viosterol 100 D daily for six days. The chemical

changes in the blood and urine are shown in the accompanying chart. It is seen that, in spite of the low phosphorus intake, there was an elevation in the concentrations of both inorganic phosphorus and calcium in the serum and an absence of phosphorus in the urine. Also, in spite of the elevation of the serum calcium the patient became nervous and irritable and on the third day of the viosterol feeding she felt cramps and tingling in the extremities. After viosterol was discontinued the serum calcium fell abruptly but the serum inorganic phosphorus remained elevated and began to appear in the urine. On the third day the patient developed active tetany and continued to have chronic tetany for the following five days during which time moderate amounts of phosphorus were present in the urine.

For the following seven days the patient was given 0.85 Gm of magnesium daily in the form of magnesium carbonate. The magnesium was given for two reasons. First it has been found that magnesium salts may relieve parathyroid tetany in animals in the same manner as do calcium salts probably by diverting the retained phosphorus to be excreted in the feces. Second it was previously demonstrated by Shelling, Kramer and Orent and Shipley and Holt⁸ that magnesium [Mg +] inhibits calci-

80 units of parathyroid extract-Collip was injected on the sixth-third day after admission and its effects on the serum calcium and inorganic phosphorus and on urinary calcium and phosphorus excretion were studied. Blood samples were analyzed at frequent intervals and each sample of urine voided during the twenty-four hour period was analyzed separately. The results, shown in the accompanying chart, illustrate the differences in behavior between viosterol and parathyroid extract. In contrast to viosterol, which increased both the calcium and the inorganic phosphorus of the serum and caused retention of the latter, parathyroid extract produced an abrupt fall in the serum inorganic phosphorus, a gradual rise in the serum calcium and an enormous rise in the excretion of phosphorus in the urine (0.888 Gm in twenty four hours, intake 0.270 Gm). On the third day after parathyroid extract administration the serum inorganic phosphorus began to rise slowly and the urine contained only traces of phosphorus. The patient was free from tetany and she was continued on the low phosphorus diet. She was discharged the latter part of December with instructions as to her dietary care at home.

The urinary calcium excretion during the periods of observation was extremely low varying between 15 and 155 mg per day in spite of the high calcium intake and in spite of the absence of phosphorus in the urine during some of the periods. On the day when parathyroid extract was administered the urine was entirely free from calcium, but on the next day, when the serum calcium rose to 8.8 mg per hundred cubic centimeters and the urine was nearly free from phosphorus the twenty four hour specimen of the urine contained but 6.4 mg.

At home the patient followed the dietary instructions for some time but later she began to eat a number of foods high in phosphorus. The

The effect of low phosphorus intake and of viosterol of parathyroid extract and of magnesium on the levels of calcium and inorganic phosphorus in the serum and on the excretion of phosphorus in the urine (case 1)

fication in vitro probably by forming an unionizable compound with phosphate and thus inactivating phosphate [PO_4^{3-}] and it was hoped that it might do likewise in the case of parathyroid tetany with phosphorus retention. The chemical changes in the blood and the urine and the clinical improvement strongly suggest this possibility. It is seen that, although the serum inorganic phosphorus was somewhat higher and the calcium lower during the magnesium period than in the preceding period in which active tetany was present, the absence of tetany was probably due to the inactivation of part of the phosphate [PO_4^{3-}] in the serum by magnesium. When the magnesium was discontinued the calcium and inorganic phosphorus in the serum continued to be somewhat elevated the urine contained moderate amounts of phosphorus and the tetany remained latent.

In order to prove or disprove the contention of Taylor and his associates⁹ that viosterol and parathyroid extract are more or less identical in their physiologic and pathologic behavior

cramps and tingling sensations soon returned and, Feb 1, 1933 after a feast of meat she was readmitted to the hospital in a state bordering on active tetany. The serum calcium was 6.6 and the inorganic phosphorus 6.9 mg per hundred cubic centimeters respectively. She was again placed on the low phosphorus diet and the tetany became latent. During her second stay in the metabolism ward, the studies with viosterol parathyroid extract and magnesium carbonate were repeated and the results were nearly identical to those found during the previous admission. When the symptoms disappeared she was again discharged home on the low phosphorus diet and because of her activities and possible breaks in her dietary regimen she was instructed to take larger doses of calcium.

CASE 2—S. M., a white woman aged 32 married, had had two normal pregnancies and deliveries. She had had symptoms of hyperthyroidism at the age of 14 and a thyroidectomy was done at the age of 20. Tetany followed soon after the operation, persisting for ten days and then gradually disappearing. At 26 following a prolonged chronic postpartum infection she had a major convulsive seizure. Since then there had been epileptiform convulsions at irregular intervals. She had also had frequent clinical signs of active and latent tetany, which were corroborated by chemical analyses of the blood. Up to

the present admission to the hospital, she had been treated with calcium, phenobarbital, bromides and parathyroid extract. The opinion of several physicians who examined her was that she suffered from both parathyroid tetany and epilepsy. The tetany and the epilepsy were usually accentuated during periods of infection. In spite of the sedatives, calcium and parathyroid extract therapy, she nearly always manifested some signs of latent tetany, such as positive Chvostek and Trousseau signs. She was admitted to the Marburg pavilion of the Johns Hopkins Hospital, Feb 8, 1932, for study. On physical examination it was found that she had bilateral choked disks, the etiology of these could not be explained but it was thought that the epilepsy and changes in the eyes were probably related. The clinical signs relative to the tetany were intermittent muscle spasms, cramps in the extremities, and positive Chvostek and Trousseau signs. February 9, the serum calcium and inorganic phosphorus were 63 and 64 mg per hundred cubic centimeters, respectively.

She was placed on a regular diet with added calcium lactate (18 Gm daily), but in spite of this calcium addition the patient still exhibited symptoms of tetany. February 12, the serum calcium was 52 and the inorganic phosphorus 55 mg per hundred cubic centimeters. February 13, the serum calcium dropped to 46 and the inorganic phosphorus rose to 64 mg per hundred cubic centimeters and on February 15 the values were 63 and 69 mg per hundred cubic centimeters, respectively. During this period she was receiving in her diet about 15 Gm of phosphorus and a total of about 2 Gm of calcium daily. February 16, the diet was changed so that the phosphorus was reduced to about 0.9 Gm daily and the calcium kept at the former level of 2 Gm, and three days later the phosphorus was further reduced to about 0.3 Gm daily. On this regimen the patient felt much better, the spasticity and the tingling sensation in the extremities diminishing considerably. February 25, the serum calcium rose to 68 and the inorganic phosphorus fell to 46 mg per hundred cubic centimeters. She was kept on this diet and in addition, 18 Gm of magnesium carbonate was administered daily. March 1, the calcium and inorganic phosphorus were 82 and 56 mg per hundred cubic centimeters, respectively. The patient's condition, so far as the tetany was concerned improved and she was sent home and instructed to follow the diet and the calcium and magnesium therapy. In November, 1932, the serum calcium and inorganic phosphorus were 90 and 47, March 6, 1933 91 and 64, June 5, 1933, 93 and 51 and Oct 10, 1933 98 and 40 mg per hundred cubic centimeters, respectively.

During her entire stay in the hospital and at home she has had several attacks of epilepsy but her symptoms of tetany have been only mild or entirely absent although parathyroid extract has been eliminated. The daily calcium magnesium therapy apparently did not interfere with normal intestinal function, since it did not produce diarrhea or constipation.

The association of epileptiform convulsions and hypoparathyroidism had been noted previously by many observers. Redlich¹⁰ collected seventy-two cases of epilepsy associated with tetany, and in twenty-two of these the combined symptoms followed strumectomy as in the case cited. A similar case has been described recently by Lissner and Shepardson.¹¹ Their patient subsequently came to autopsy and, except for a few small atherosclerotic plaques in the smaller basal blood vessels, there were no pathologic changes in the brain.

Two other cases of tetany were treated with the low phosphorus diet but, as metabolic and follow-up studies in these were not possible they will not be discussed in detail. However, the clinical results during the short periods of observation were quite striking after the change to the low phosphorus diet. In both of these the tetany followed strumectomy for hyperthyroidism and before dietary control was instituted both required frequent administrations of parathyroid extract and large doses of calcium salts.

COMMENT

As early as 1891, Horsley¹² divided animal species with respect to their reaction to thyroidectomy (in reality thyroparathyroidectomy) into four classes and attributed these variations in symptoms to the dietary habits of the different species. Carnivora developed acute tetany much sooner and fared worse than did herbivora. Horsley's views gained support from the observations of Breisacher¹³ that dogs fed meat diets before and after thyroidectomy (thyroparathyroidectomy) suffered more severely and succumbed much sooner than did those fed milk. These observations were repeatedly confirmed by many investigators. However, the deleterious effects of meat are usually attributed to the formation of toxic protein metabolic end products which are not destroyed in the absence of the parathyroids,¹⁴ and the beneficial effects of milk are thought to be due to the presence in it of detoxifying agents or the secretions from the parathyroids.¹⁵ It must be apparent, however, that the detrimental or beneficial effects attributed to these substances are due not to hypothetical ingredients but to the calcium and phosphorus that they contain—a fact previously pointed out by MacCallum,¹ Greenwald,² Salvesen¹⁶ and Shelling^{3a}. Thus, meat is more conducive to tetany because of its high phosphorus and extremely low calcium contents, and its ingestion would therefore favor phosphorus retention, which the parathyroprivic organism is unable to excrete except as an insoluble salt with calcium, in the latter of which meat is lacking. On the other hand, the partial alleviation of tetany by feeding moderate amounts of milk is due primarily to its high calcium content, although it does contain an appreciable amount of phosphorus because of this relatively high phosphorus content milk by itself seldom alleviates tetany completely, unless appreciable amounts of calcium salts are also added.

But in spite of these evident facts in regard to the importance of phosphorus in tetany, very little attention is paid to this element in the dietary treatment of parathyroprivic tetany in human beings. Even in metabolism studies¹⁷ in which the intake of calcium is controlled milk and other food substances are frequently added in large amounts in order to increase the calcium intake without cognizance of the fact that these articles of diet also contain large amounts of phosphorus, which the parathyroprivic organism is unable to cope with unless large doses of parathyroid extract and calcium are administered at the same time. This lack of appreciation of the relation of phosphorus to parathyroid function¹⁸ may account, in part, for the occasional failure of calcium and parathyroid extract therapy in parathyroprivic tetany. Such resistance to treatment has been reported by Hjort and Eder.¹⁹

18 It is interesting that in Queries and Minor Notes (J A M A 100 1957 [June 17] 1933) a salt mixture in which diodium phosphate is included was recommended for the treatment of parathyroid tetany. The proportions of calcium to phosphorus in this salt mixture is about 2:1 apparently the purpose of adding phosphate was to bring the calcium phosphorus ratio to that contained in bone. It was not realized however that the addition of disodium phosphate and sodium bicarbonate to an equal amount of calcium gluconate doubles the amount of salt taken daily (23.4 Gm) and serves no purpose in amelioration of tetany in fact it increases the daily requirement of calcium and parathyroid extract since about 0.650 Gm of phosphorus is added to the diet daily.

Snell²⁰ John,²¹ Aub,¹⁷ Sahlgren,²² Lissner and Shepardson¹¹ and others

Hjort and Eder's patient received a low protein diet, 3 quarts of milk, from 30 to 40 Gm of calcium lactate and parathyroid extract as high as 130 units daily. But in spite of this therapy they state that "a calcium rich diet and rest proved unavailing" and that "parathyroid extract, 130 units daily, failed during the course of a week to induce any appreciable rise in the serum calcium." While it is quite true that the 3 quarts of milk contributed more than 30 Gm of calcium daily, it is equally true that it contained nearly the same amount of phosphorus. Since the effect of parathyroid extract is reflected in a reduction of the serum inorganic phosphorus by excreting it primarily in the urine as may be seen from the accompanying chart, the greater the phosphorus intake and retention the more parathyroid extract would be necessary to relieve the tetanic manifestations. Similarly, if the beneficial effects of calcium in parathyroid tetany are due to its ability to eliminate the retained phosphorus by way of the bowel as the insoluble phosphate the increase in phosphorus intake will, of necessity, impair the efficacy of each gram of calcium ingested. Had a low phosphorus diet been given, much less calcium and parathyroid extract would have been required to alleviate the tetany and to maintain a nontetanic calcium level in the serum.

Snell's patient received a general diet, much milk, vegetables, and from 10 to 30 Gm daily of calcium lactate. On this regimen the calcium rose but slightly—from 4.8 to 6.7 mg per hundred cubic centimeters. When from 200 to 400 units of parathyroid extract was administered daily, the serum calcium rose and the inorganic phosphorus declined and, in order to keep the serum calcium above tetanic levels, it was necessary to continue with 14 Gm of calcium lactate and 100 units of parathyroid extract daily. Obviously, as in Hjort and Eder's case, the diet contained, aside from large amounts of calcium, much phosphorus hence the requirement of such large doses of calcium and parathyroid extract.

The refractoriness of Aub's patient to parathyroid extract is of considerable interest, since what Aub and his associates term "immunity" to the extract may also be explained as due to a greater phosphorus intake and retention during the period of "immunity." Their data on intake and output of calcium and phosphorus are complete, so that this point may be ascertained. Reference to their table 1 (K L) shows that (1) during the low-calcium periods (intake 0.33 Gm) the phosphorus intake varied from 1.34 to 2.49 Gm, (2) when, in the later periods, the calcium of the diet was increased to 2.25, the phosphorus intake was also increased, in some instances to 3.89 Gm, (3) during the period when parathyroid extract was effective, the phosphorus intake was but 1.34 to 1.63 Gm, and when it became ineffective the phosphorus intake was more than doubled and (4) the calcium concentrations in the serum were higher and the inorganic phosphorus lower during the low phosphorus periods in spite of the fact that during the latter periods the calcium intake was seven times that partaken in the earlier periods. A similar resistance to therapy also existed in their second patient (B W). During the low calcium periods his phosphorus intake was between 1.04 and 1.94 Gm but

when the calcium was increased from 0.30 Gm to 6.0 Gm the phosphorus was also increased to as high as 6.47 Gm. On the latter regimen, in spite of the twenty fold increase in calcium in the diet and in spite of the administration of thyroxine (which supposedly was effective in elevating the serum calcium in the earlier periods of study), the calcium and phosphorus in the serum remained at tetanic levels. Obviously aside from the possibility of a development of immunity or resistance to parathyroid extract the inefficacy of the therapy may well be accounted for by the increase in the phosphorus intake or by other factors conducive to hyperphosphatemia.

The relation of the phosphorus intake to the resistance to therapy in the other reported cases is difficult to ascertain since in most instances the dietary regimens are not mentioned or are not given in detail. In Lissner and Shepardson's patient, it is difficult to determine whether the refractoriness to parathyroid extract was due to phosphorus intake or to the concomitant fever which may have resulted in the liberation of considerable amounts of phosphorus from tissue breakdown.

The difference in the response of the first patient to calcium, magnesium, parathyroid extract and vitamin D is illustrated in the accompanying chart. It is seen that (1) during the high calcium-low phosphorus periods there was a reduction in the serum inorganic phosphorus with little or no phosphorus in the urine, indicating that the removed phosphorus was probably excreted in the feces as the insoluble calcium salt, (2) during the magnesium period there was no phosphorus in the urine in spite of the retention of phosphorus in the blood and in spite of the absence of tetany. In this case as explained previously, magnesium probably inactivated part of the phosphorus in the blood and also aided by the excretion of phosphorus in the feces, (3) effects of parathyroid extract are primarily on the phosphorus and the elevation of the serum calcium usually follows the reduction in the serum inorganic phosphorus, which was brought about by excretion in the urine and (4) vitamin D not only elevates the serum calcium but also increases the phosphorus retention as indicated by the absence of phosphorus in the urine and by the elevation of serum inorganic phosphorus during the cholesterol feeding period. For this reason, vitamin D should be used cautiously, or not at all, in the treatment of parathyroid tetany. The dangers of the injudicious use of vitamin D in parathyroid tetany, in renal rickets and in nephritis with phosphorus retention have been discussed elsewhere.²

The advantages of the low phosphorus diet in the treatment of parathyroid tetany are as follows: 1 It prevents phosphorus retention and thereby allows the serum calcium to approach nontetanic levels. 2 Less calcium is needed to rid the body of the retained phosphorus as the insoluble salt. 3 It minimizes or dispenses with the use of parathyroid extract in cases with marked phosphorus retention and thus reduces the possibility of metastatic calcification and renal impairment. 4 It obviates the use of vitamin D, since its administration in the presence of phosphorus retention may predispose to metastatic calcification. 5 The diet may be derived from a variety of food substances and thus eliminates the monotony of eating the same articles of food daily. 6 The treatment may be con-

tinued at home without inconveniencing the patient and without the need of too frequent analyses of the blood for calcium, as when parathyroid extract is used

Menus for low phosphorus diets may be easily calculated from tables given by Sherman²⁴ and Simmonds²⁵

The added calcium may be given as the lactate or carbonate and the magnesium as the lactate, carbonate or oxide

The low phosphorus diet may be used after thyroidectomies to prevent transient or permanent tetany, in renal rickets and in nephritis with phosphorus retention. The use of high calcium diets for the treatment of nephritis with phosphorus retention was previously suggested by Briggs²⁶

SUMMARY

1 Two patients with parathyroid tetany have been treated with low phosphorus diets

2 Studies were made of the effect of calcium, magnesium, parathyroid extract and vitamin D on the concentration of calcium and inorganic phosphorus in the serum and on the excretion of these substances in the urine

3 There are certain theoretical and practical advantages of the low phosphorus diet

4 The low phosphorus diet is also recommended in cases of renal rickets and nephritis with phosphorus retention

CHRONIC NONTUBERCULOUS BRONCHOPNEUMONIA

DAVID RIESMAN, M.D., Sc.D.
PHILADELPHIA

For a number of years I have been interested in a form of disease of the lungs which has not received much attention at the hands of systematic writers. An early paper published in 1913¹ was followed by a few corroborative articles, but it is only within recent years, chiefly through the conjoint work of the roentgenologists and the clinicians, that the frequency and the importance of the condition have been recognized.² In the earlier paper, my conclusions were as follows:

1 The disease is a confluent lobular pneumonia of lobar distribution characterized by long duration, low fever, and the following physical signs: impairment of resonance, bronchovesicular breathing and showers of crackling rales. 2 It must be looked on as one of the causes of obscure long-continued fever. 3 The disease always seems to end in complete recovery both symptomatically and anatomically. 4 In the beginning typhoid may be suspected in the later stages, tuberculosis. 5 The disease is, I believe, often overlooked, owing to the fact that the lower posterior aspects of the chest are seldom examined in ambulatory cases, especially when the symptoms are rather trivial. I am quite sure the diagnosis of tuberculosis is often made in these cases of chronic cough, with low, continued

fever, but if the chest is carefully examined, back and front, above and below, the peculiar, almost specific character of the disease will be discovered, and then the thought of tuberculosis will be no longer entertained. (Of these, further experience has shown that the third is too optimistic.)

The disease derives its importance from the fact that it is a cause, at least a possible one, of prolonged ill health; furthermore, it may lead to the diagnosis of tuberculosis and to useless as well as costly confinement in a sanatorium, and, finally, it is a cause of recurrent colds. Until a few years ago it was not known that this type of pulmonary disease might be related to infection in the paranasal sinuses. Ignorance of this fact was in some degree responsible for the not infrequently unsatisfactory results of treatment.

The disease is most common in children and young adults but is encountered at all ages. I have at present under my care two men, aged 54 and 65, in whom the disease presents all the characteristic features.

Physical examination in a typical case shows the signs confined to a lower lobe, perhaps the left more often than the right. There is slight impairment on percussion, and the tactile fremitus is normal, increased or diminished. The most striking feature presents itself on auscultation, then one hears many moist râles, either fine and sticky or coarse, and more abundant after coughing. The voice sounds may be diminished, normal or increased. In the whole picture nothing is really significant or important on examination except the rales of lobar distribution.

ETIOLOGY

In my first paper I looked on the disease, which I then called a lobar form of bronchopneumonia, either as a direct sequel of influenza or as due to primary infection with the influenza organism or with other common varieties of bacteria, chiefly the pneumococcus and the streptococcus. I am excluding from consideration here the inflammatory diseases of the lungs caused by yeasts, fungi, *Streptothrix*, *Coccidioides* and other organisms of similar nature, as they rarely show lobar or unilateral distribution. Psittacosis is also not included, as that generally runs an acute course and presents a much graver clinical picture.

With wider experience I have learned a few facts that are important in understanding the causes of the disease in question. In the University Hospital through the cooperative study of the roentgenologists Drs. Pancoast and Pendergrass, we have come to feel that the majority of cases of the chronic type of bronchopneumonia are associated with disease of the sinuses, and we are inclined to believe that the sinuses are often the primary factor in the morbid process. This idea is not entirely new but was suggested by a French writer a few years ago, his name I do not recall. At the present time it is well known to a number of roentgenologists and to pediatricians and tuberculosis specialists, as well as to laryngologists and bronchoscopists.

Now that the x-rays have revealed the presence of infection in the accessory nasal sinuses in association with chronic lung infection, and since improvement follows the clearing up of the sinus trouble, the conclusion seems justified that the two are connected as cause and effect, that is the view of Manges.³ The Dunns⁴

among other effects of paranasal sinusitis, mention bronchitis, acute and chronic (occasional misdiagnosed tuberculosis), bronchiectasis and lung abscess. One must admit the possibility that the two conditions may be present without being dependent one on the other. In all probability influenza may become a localized, subchronic process in the lung. It is also possible that the lung disease, whether influenzal or not, may be primary and the sinus disease secondary.

While in many instances the sinus involvement is clearly indicated by the symptoms, especially in persons with a history of frequent colds, there are many cases in which the involvement would escape detection if roentgenograms were not taken, hence the importance of making in every case of these chronic lung infections, or in recurring colds in children, roentgenologic study of the paranasal sinuses. The following case shows the value of such an examination even in a young child.

CASE 1—E. H., a girl aged 2 years, had been short of breath since the age of 3 months. She had had repeated attacks of pneumonia, dyspnea and bronchitis followed after the second attack of bronchopneumonia.

A roentgenogram showed a marked increase of the hilus and trunk shadows, probably a tracheobronchitis from a sinus infection. In an older person the appearance could have been due to bronchiectasis. A roentgen examination showed that the frontal sinuses had not developed, the ethmoids were clouded on both sides, the maxillary sinuses were probably clouded on both sides, an opaque foreign body, a button, was seen in the left nasal passage. Four days later the button had disappeared, unsuccessful attempts were made to find it. Three months later the ethmoid cells were much clearer and the maxillary sinuses had cleared up. Five months later the condition was improved but by no means normal; there was still a purulent tracheobronchitis. The child had also had some asthmatic attacks.

Can the disease occur at the apex? There is no inherent reason why it should not, but just as tuberculosis prefers to begin its work in the upper lobe, so this condition of which I speak, chronic or subacute bronchopneumonia of lobar distribution, prefers the lower lobe. It would be difficult, except by prolonged observation, to differentiate between tuberculosis and the process in question when the upper lobe is involved. A few cases have been described in the German literature in which, through accidental death, an opportunity for autopsy was given and the process proved to be a nontuberculous pneumonia. Jacobi describes chronic pneumonia located in the apical region especially on the right side, as a frequent occurrence in children. I doubt, however, whether he would today give his explanation of thirty years ago that these lesions are nontuberculous and result either from a bronchopneumonia or from a syphilitic process. To him, syphilitic disease of the lung apart from pneumonia alba of infants was a common occurrence. Today it is known that syphilis of the lung is rare and difficult of diagnosis. The most recent textbooks do not mention it as a possible factor in the case of chronic pneumonia. I am inclined to think that, even though the disease in the cases described by Jacobi did not look like tuberculosis, the majority were due to that type of infection.

CLINICAL COURSE

For a certain group of cases this has been well set forth by Allen K. Krause.⁶ The patient usually complains of some impairment of health, which he may

date back to an attack of influenza. In children it may have followed measles or whooping cough, simple bronchitis or bronchopneumonia. From that time on the patient may have been subject to repeated colds, although often this tendency is outgrown even though the physical signs of a basal lesion remain. The cough may be slight or severe, or it may be absent. Expectoration is also scanty, rarely it is blood streaked. The loss of flesh is minimal. In many cases there is hardly anything to call attention to the lungs. At times there is a protracted subfebrile course—a temperature between 99 and 100 F. for weeks—suggesting a low grade typhoid fever or tuberculosis. A roentgen examination may show very little—some haziness, perhaps of the lung markings, but in severe cases that have lasted a long time fibrotic changes, adhesions to the diaphragm and bronchiectatic cavities may be discovered.

Dr. J. Alexander Miller⁷ has suggested a good classification of chronic nontuberculous lung disease. He divides the cases into (a) subacute, (b) subacute with recurrences and (c) chronic. My own cases very readily fall into these three groups.

The disease usually terminates in recovery, but the spot originally affected remains a locus minoris resistentiae, so that whenever the individual has a cold or bronchial attack the old area will again show physical signs, especially showers of rales. It is not at all certain as Betty Shaw observes, that the recurrent attacks in such patients are the result of reinfection from the outside. They may be recrudescences of the existing internal infection. Many patients may become chronically bronchitic and are in fact carriers. The infection is a reinfection from within.

When complete restoration does not occur the inflammatory process may penetrate more deeply and may eventually lead to definite bronchiectasis from which full recovery is unlikely, hence the importance of early recognition and treatment. In a discussion of the subject with an "allergic" friend, he made the suggestion that some cases of asthma might take their origin in the disease I am describing. My personal experience suggests that this is quite probable.

I can illustrate the condition by citing a few cases.

CASE 2—J. R., a man aged 52, came under my observation in 1919 complaining of dyspeptic symptoms and constipation. He has been under my care ever since. His lungs were normal until October 1929 when he had cough with expectoration and a subsiding neuritis of the right brachial plexus. At that time I found scattered rales through the right side of the chest but much more marked over the left side posteriorly. These rales continued and were eventually limited to the left side of the chest. The sputum was free from tubercle bacilli. On his occasional visits I found nearly always the same sticky moist rales over the left base with a little pain on that side. The vocal resonance and breath sounds were increased. Just a year ago he had a shower of moist rales in the left base although his chief complaint was indigestion, regurgitation of food and intermittent irregular heart beats. (He had an attack of erysipelas in the spring and another one during the summer.) Only last summer the chest began to become clear. Roentgen examination revealed a marked increase in density at both bases with intensification of trunk shadows and bilateral cervical rib.

CASE 3—L. A., a young man who has been under my care since he was a little boy, coughed a good deal and had an asthmatic tendency in his early years, his sinuses were bad. For years, physical examination showed at the right base posteriorly impaired resonance and subcrepitant and sonorous rales.

⁵ Jacobi, Abraham. Arch. Pediat. 20, 1903.
⁶ Krause, A. K. Tr. Am. A. Physicians 46, 227, 1931.

⁷ Miller, J. A. Am. J. M. Sc. 154, 805 (Dec.) 1917.

and increased tactile and vocal fremitus. Whenever he had the slightest cold I was able to find the same type of rales at the right base. Roentgen examination of the chest showed a definite area of increased density at the right base strongly suggestive of a chronic pneumonic process. There was no suspicion of a tuberculous process in the apex, the trunk shadows were somewhat intensified but there was no mottling found at their distributions. The rales were still present in 1928, a matter of sixteen years since the boy had come under my observation, but by about 1930 after treatment of his sinuses they disappeared.

CASE 4—S S, a man, aged 45, a tailor and native of Russia, came under my observation in 1923. He had a 4+ Wassermann reaction and his chief trouble was indigestion. In February 1924 he came to see me on account of a cold and sore throat. The heart was rapid 112, the temperature, 98.4, the blood pressure, 135 systolic, 60 diastolic, he weighed 135 pounds (61.2 Kg). Physical examination showed as the most interesting finding showers of fine and bubbling rales over the lower lobe of the left lung, tactile fremitus and vocal resonance were normal over this area. This condition persisted for a long time. Not until May 1924 was there a note in my record that the rales had practically disappeared. Later he came on account of a cough. The rales were again present in quantity over the left lower lobe posteriorly and the percussion was slightly impaired. There was tenderness over the right maxillary sinus. In the spring of 1925 the rales were very much diminished. In July he complained of burning in the epigastrium, a coated tongue and constipation. Again numerous rales were present over the left side of the chest, although he did not complain of any respiratory symptoms. In 1927 the rales were very few. At the end of 1927, after a hot bath he became a little hoarse. Examination showed a number of moist rales in the same area as in the past. They disappeared within a month. In the spring of 1928 his chest was entirely clear also in June 1930. His last visit was in April 1933 and at that time I found his chest normal on examination.

CASE 5—L T, a man aged 36 married, complained, Dec 7 1931 of cough and expectoration. He had been well except for frequent colds until June 1931 at which time fever, cough and expectoration developed and he was put to bed. The cough, the expectoration and the irregular fever continued for five or six weeks. Then the temperature gradually became normal but the cough and expectoration persisted. His physician stated that there were rales throughout the left lung. A roentgenogram taken at that time was said to have shown tuberculosis. With abatement of the fever he was allowed up, but the cough and expectoration which was never blood streaked, persisted with occasional evening rises of temperature to 99.5 F. Physical examination showed a good deal of pus draining from both ethmoidal areas and from the left sphenoid. Both antrums were opaque on transillumination. Examination of the chest showed slight impairment at the left base and the left axilla with diminution of breath sounds and a few rales. The blood was within normal limits. The sputum was repeatedly found negative for tubercle bacilli and on culture showed a pure growth of influenza bacilli. Roentgen examination of the chest showed slight haziness of the left lung field with exaggeration of trunk shadows to the left base. The patient was admitted to the hospital where a bilateral ethmoidectomy and a bilateral antrum drainage were instituted. Rapid recovery from these operative procedures ensued. It was followed by a course of autogenous vaccine made from the secretion from the ethmoids and antrums. Since then the patient has been seen repeatedly. He has been free from colds. His nose and throat physician Dr. H. P. Schenck reports that the condition of his nose is satisfactory. There are now no symptoms and physical examination is entirely negative.

Here is a history of an illness of seven months duration characterized by a low grade pneumonitis limited to one lower lobe and associated with extensive sinus disease. The case was mistaken for tuberculosis. Dr. Pancoast who studied the case roentgenologically,

writes: "On reviewing the history and the course of the disease as judged from the physical signs, which are rather characteristic with the finding of extensive sinus disease, which we know to be an etiologic factor in this type of nontuberculous basal pneumonitis, we would call this Riesman's pneumonia."

Diagnosis in such cases is impossible for the man who examines only the front of the chest or the front and the supraspinous fossae. Only by the unvarying routine of examining the entire chest, back and front, above and below, will the condition be discovered. When signs are found in the lung, roentgen examination of the chest should be made. A roentgenogram as well as specialistic study of the sinuses is also desirable.

In the differential diagnosis, some of the dust-inhalation diseases, and infections with organisms of the streptothrix, leptothrix and blastomyces and coccidioides groups must be kept in mind. The differentiation may require frequent sputum examinations as well as sputum culture on special mediums. When a definite sinus disease exists, the conclusion that the case is of the simpler type of chronic pneumonitis is usually justified. In expert hands the fluoroscopic examination with study of roentgenograms may prove of the greatest help.

Tuberculosis comes into the picture whenever the disease runs a protracted course. However, a primary tuberculosis of the base is exceedingly rare. Norris and Landis deny its occurrence in adults, but Lawra-son Brown,⁸ Lyman⁹ and Jacob⁹ have observed it, I myself have seen two or three cases. Nevertheless, the presumption should always be that a basal lesion is not tuberculous unless a sputum examination reveals the presence of tubercle bacilli.

TREATMENT

Rest in bed is demanded in the febrile and usually in the subacute cases and in cases, febrile or not presenting acute exacerbations. Locally, counterirritation may prove useful—mustard or a weak iodine application. For the cough a simple remedy with creosote may be used, when the cough has been severe, I have found the following combination helpful: terpin hydrate, 2 Gm. and codeine sulphate 0.12 Gm., the ingredients are mixed and divided into twelve capsules. One is given every three hours.

If there is sinus infection, local treatment by a competent specialist is indicated. I am rather averse to radical measures although opening of an infected antrum in a radical manner may be advisable.

Attention to the general health, with special efforts to prevent recurrent colds, is of prime importance. Regulation of exercise, work and play is required, cold bathing and massage are useful. The diet should contain an abundance of vitamins and cod liver oil in the cold season and viosterol at other times. Vaccines prepared from sinus secretion or sputum or stock vaccines often work beneficially. Climatic therapy is useful. Florida, California and parts of Arizona are good winter climates. For those who cannot afford to go away the sun lamp may prove useful. In the summer season I have found the rocky coast of Maine and of Massachusetts to exercise a beneficial influence. But in addition to all other forms of medicinal or climatic treatment, psychotherapy occupies a prominent place.

⁸ Per oral communication to the author.

⁹ Jacob, M. Med. J. & Rec. 129:32 (Jan. 2) 1929.

When the process has gone beyond the curable stage and bronchiectasis has developed, therapy is more difficult. The bronchoscopist, even the thoracic surgeon, may be needed. I shall, however, do no more than mention this phase of treatment.

ABRUPTIO PLACENTAE FOLLOWING ACUTE PLACENTAL INFARCT

CESAREAN SECTION, STAPHYLOCOCCUS AUREUS SEPTICEMIA, RECOVERY FOLLOWING TRANSFUSIONS FROM IMMUNE DONORS

R A BARTHOLOMEW, MD

ATLANTA, GA

This case is deemed worthy of reporting for the following reasons: 1 It supports the theory¹ that abruptio placentae is the result of poisonous split products of placental protein, particularly histamine elaborated during the autolysis of an acute infarct on the maternal surface of the placenta. 2 It illustrates the conditions warranting the use of cesarean section rather than slower conservative measures in the treatment of abruptio placentae. 3 It illustrates the ever present possibility of infection following cesarean section, even in a clean case. 4 It illustrates the apparently life-saving value of blood transfusions, particularly from donors immunized against the specific organism by vaccine treatment.

Mrs W D, aged 24, a primigravida, had reached the ninth month of pregnancy without any evidence of toxemia or other complications. At 10 p m May 26 1932 her husband reported that she had suddenly felt very weak. There had been no edema or headache. Following the administration of a mild sedative she slept well. After breakfast the following morning a severe and constant pain developed over the entire abdomen associated with weakness, nausea and vomiting.

When seen at 10 30 a m May 27 the patient was lying in bed. An expression of anxiety and distress and a gray pallor gave evidence of some complication of a serious nature. The blood pressure was 120 systolic 70 diastolic, the temperature 98 pulse, 106, respiration rate, 22. The abdomen was of normal size and contour for a pregnancy of eight months duration. Palpation showed the uterus to be uniformly rigid and tender. There were no labor pains. The fetal parts and heart sounds could not be obtained. The fetal movements had not been felt since the onset of the pain. There had been no vaginal discharge. Rectal examination showed the cervix to be short and undilated. A diagnosis of abruptio placentae with concealed hemorrhage and intra-uterine fetal death was made. The patient was given morphine, one-sixth grain (0.01 Gm), and scopolamine, $\frac{1}{200}$ grain (0.0005 Gm) by hypodermic injection and sent to the hospital.

On account of the evidence of concealed hemorrhage and undilated cervix and the absence of labor pains, the classic cesarean section was deemed to be preferable to a slow induction of labor and conservative treatment. A catheterized specimen of urine showed one plus albumin. The blood pressure had dropped to 100 systolic, 70 diastolic. Thirty cubic centimeters of 4 per cent mercurochrome was injected into the vagina. When the abdomen was opened under ethylene anesthesia, a small amount of blood tinged serous fluid escaped. The uterus was in a state of tetanic contraction and showed a mottled appearance due to hemorrhagic areas under the peritoneum and marked dilatation of the veins. The placenta was completely separated from the uterine wall by large dark clots and fluid blood, and the patient was delivered of a still born male infant weighing 6 pounds (2720 Gm). The blood pres-

sure had dropped to 70 systolic, 50 diastolic at this stage of the operation and 500 cc of acacia-dextrose solution was given intravenously to combat shock. The uterus contracted well with the aid of solution of pituitary, and there was no excessive bleeding during repair. The patient reacted well and her condition improved rapidly after operation. On the third day the temperature was 98 pulse 80 and respiration rate 20.

On the fourth day May 31 the temperature pulse and respiration increased to 102, 140, 24 with a further rise to 104 145 25 on the fifth day. Marked herpes appeared on the lips and the patient complained of constant headache weakness and occasional chills. There were no localizing symptoms or observations to explain the condition the abdomen remaining soft and the lungs clear. Examination of the blood showed 2 230 000 red cells 15 500 white cells and 6 Gm of hemoglobin.

June 1 the patient was given a transfusion of 300 cc of whole blood. Blood culture June 2 yielded a growth of hemolytic *Staphylococcus aureus* within forty eight hours which was verified by further cultures on June 3, 4 and 5. Subcultures were taken from these growths and a vaccine was prepared. Meanwhile the patient was given a second transfusion (300 cc) June 3 and third (320 cc) June 7 and a fourth (400 cc) June 9. During this time the red cells increased to 3 000 000 the white cells to 19 000 and the hemoglobin to 8 Gm. The temperature was intermittently high ranging from 100 to 104 the pulse from 115 to 125 and the respiration rate from 20 to 25. There were no chills after June 6 but on this date a small amount of pus was obtained from the lower end of the wound and there was marked superficial and deep seated tenderness over the pubic region and vulva.

In the meantime three donors had been immunized by daily injections of the vaccine beginning with 0.25 cc (125 000 000) increasing 0.25 cc daily up to and continuing with 1 cc daily. After receiving daily injections of vaccine for at least one week these donors were used for transfusions of 240 cc. June 11 320 cc June 13 240 cc June 15, and 260 cc. June 18. The opsonic index of one of the immune donors June 15, was found to be 19 whereas that of the patient, June 16, was 17. Blood cultures, June 13 and 18 showed no growth.

June 12 the patient complained of sharp pains in the right axilla on breathing. Auscultation showed rales and a slight friction rub. This symptom disappeared within two days. From the date of the first transfusion with immune blood June 11 the fever became remittent in type and except on June 15 (103.5) ranged from 98 to 101 and remained normal after June 20. The patient was discharged June 25.

Examination of the placenta showed an acute brown red infarct exposed on the maternal surface of the placenta and definitely demarcated from the surrounding normal placenta. The consistency was more homogeneous and slightly firmer than the surrounding normal placenta. Microscopically, the villi showed dilated engorged and occasionally ruptured capillaries and veins severe necrosis of the syncytium, Langhans layer and the stroma. There was an absence of intervillous hyaline substance which apparently characterizes infarcts of acute development. The presence of this type of lesion exposed on the maternal surface of the placenta, probably permits a concentration of the poisonous split products of placental autolysis particularly histamine on the decidual sinuses in contact with the lesion. The dilatation and rupture of the sinuses from the action of histamine probably brings about extravasation of maternal blood at the placental site, with resulting abruptio placentae.¹

Blood transfusions have long been considered the most efficient means of conserving and increasing the patient's resistance during the course of blood stream infections particularly in those infections accompanied by rapidly developing anemia, and in many cases have undoubtedly averted an otherwise fatal outcome. However, if specific immune bodies can be developed in the donor by the injection of a vaccine prepared from the specific organisms obtained from the patient's blood culture, it is reasonable to believe that such specific immunotransfusion would be of greater value than any other possible measure.

¹ Bartholomew R A and Kracke R R The Relation of Placental Infarcts to Eclamptic Toxemia Am J Obst & Gynec 24 797 (Dec) 1932

Immunotransfusion is by no means new, as reports have appeared in the literature, from time to time, bearing out the value of this method. It is probably true, however, that the apparently successful cases are reported much more frequently than the failures, making it difficult to arrive at a true estimate of the value of the treatment, as compared with ordinary blood transfusions. Brody and Crocker² recently reported in detail the apparently favorable response in a case of *Streptococcus haemolyticus* septicemia, in which ordinary blood transfusions and various other measures seemed of no avail. They also refer to other reports, illustrating the value of immunotransfusion.

In the case here reported the patient showed more rapid improvement, both subjectively and objectively, coinciding with the use of immune donors. The rapidly fatal outcome in some cases makes it impossible to secure a positive blood culture, prepare a vaccine, immunize one or more donors and give the patient the benefit of immunotransfusions. It would seem advisable, however, to obtain the specific organism by blood culture as early as possible in the course of the illness and, in the meantime, use ordinary blood transfusions to keep up the patient's resistance until donors can be immunized with the specific vaccine.

POSTERIOR PITUITARY IN PYELITIS

USE OF EXTRACT FOR ACCELERATION OF
DRAINAGE AND RELIEF OF PAIN

WARD DARLEY, M D

AND

WILLIAM B DRAPER, M D

DENVER

It is conceded by many authors that atony of the musculature of the renal pelvis and ureter with the resultant sluggish drainage of these structures plays an important role in the development and course of pyelitis. The efficacy of drainage induced by ureteral catheterization in the treatment of this condition is well established. Unfortunately, however, this procedure requires a technical skill and specialized apparatus which are often beyond the resources of the general practitioner. For this reason a simpler method available to any physician for accelerating the drainage of these structures would be of obvious value.

It has long been known that the pelvic and ureteral musculature in common with smooth muscle elsewhere in the body is responsive to systemically administered drugs, and certain depressants of the parasympathetic innervation, particularly atropine have found a wide employment in the treatment of excessive muscular activity of these structures. It is surprising, therefore, that until recently little attempt has been made to investigate the possibilities of the augmentor group of drugs in the therapeutics of the opposite condition of atony.

The autonomic reactions of the isolated ureter have been studied by a number of investigators. Satani¹ has shown that an augmentor response occurs to both the stimulants of the sympathetic and the parasympa-

thetic nerve endings. Accordingly, an increase in the tone and peristaltic activity of the isolated organ is seen when either epinephrine or physostigmine is added to the bath. The subject has also been recently investigated by Gruber,² who has shown that the ureteral muscle responds with augmentation to the myotropic drugs histamine and solution of pituitary. Recently a similar response of the renal pelvis and ureter in situ has been observed by a number of workers. Reimann³ has shown by serial roentgen studies on the normal human subject that the pelvic and ureteral shadows obtained after intravenous *ioapan* rapidly disappear after the subcutaneous injection of postpituitary extract. Jona and Flecker⁴ have demonstrated that in dogs the oscillations of the intrapelvic and intra-ureteral pressure are increased by intravenous solution of pituitary, morphine, strychnine and especially physostigmine. They interpret their observations as indicating that these drugs cause increased peristalsis of these structures. In a number of cases of pyelitis in human beings these authors, by direct observation under the fluoroscope after the intrapelvic instillation of sodium iodide, determined the particular drug that in each case gave the best contraction of the pelvis and ureter and administered this to the patient. "Patients who for years had failed to obtain relief from the usual recognized forms of treatment derived immediate relief in this way."

The treatment of pyelitis by the subcutaneous injection of postpituitary extract was first advocated in 1928 by Miller.⁵ He successfully treated with solution of pituitary nine adult patients having recurrent pyelitis who had failed to obtain relief from the usual methods of treatment. Following this lead, Ginsberg⁶ similarly treated a 2 year old child who had been acutely ill with pyelitis for twenty-six days. The resultant clinical improvement was prompt. The observations of Reimann, previously referred to, have been confirmed. Studies show that following the intramuscular injection of 1 cc of solution of pituitary or ampoules of pitressin the pelvic and ureteral shadows produced by intravenous *ioapan* in normal human subjects disappear or are markedly diminished in from three to seven minutes. A case of infected hydronephrosis is described in which symptomatic relief, especially of pain, repeatedly followed the exhibition of the solution.

In this communication further studies are reported on the therapeutic value of postpituitary extract in pyelitis. Our series consists of fourteen adults and two children and comprises seven cases with no history suggestive of a previous pyelitis, five cases of recurrent pyelitis, one case of postpartum pyelitis and three cases of postoperative pyelitis. All these patients presented the well defined symptom complex that is characteristic of pyelitis. The diagnosis could have been strengthened by preliminary ureteral catheterization, but we were attempting to evaluate a nonsurgical method of drainage and this procedure would have impaired the validity of our control observations.

In the interests of brevity, our sixteen cases have been summarized in the accompanying table. The solution was administered subcutaneously in doses ranging from 3 to 15 minims (0.2 to 1.0 cc). The intervals between injections varied from four to eighteen hours, and they were continued until all signs of acute illness

The following pertinent facts are evident from a analysis of our data. In nine of the sixteen cases presented (1 to 9, inclusive) the usual medical treatment, including alkalis and urinary antiseptics, had been given a clinical trial for periods ranging from two to twenty-eight days (an average of eight days) without relief of

Summary of Cases*

Clinical Progress While Under Observation

Case	Sex and Age	History and Character of Attack	Number of Attacks Observed	Treatment in Hospital Prior to Pituitary Therapy	Drugs Administered Simultaneously with the Solution of Pituitary	Results of Extract Therapy			
						Duration of Pain Prior to Solution of Pituitary	Approximate Time for Relief of Pain	All other notes	
1	♀ 23	Recurrence while under observation fever vomiting, right sided pain	One	Methenamine for 2 days no relief	Alkaline mixture	12 q t h	2 days	1 hr permanent	Temperature normal in 4 days
2	♂ 38	14 days after prostatectomy fever vomiting bilateral pain	One	Methenamine for 2 days then alkaline mixture for 4 days no relief	Alkaline mixture	12 q t h	6 days	4 hr permanent	Temperature normal in 3 days

* Pain in each instance characteristic of pyelitis.
† Treated outside hospital by private physician.

All patients were placed on a large fluid intake during observation. Details of treatment unknown.

had disappeared. Fever, urinary pus and albumin were common to all cases, and data regarding these are not given except as they may have been modified by treatment. The majority of the patients could not be followed subsequent to their discharge from the hospital, and we can speak, therefore, only of clinical or symptomatic relief and not of a permanent bacteriologic cure.

pain or other apparent benefit. This is in sharp contrast to the relatively brief interval of from one to four hours (an average of approximately two hours) between the exhibition of the solution and the therapeutic response as indicated by the relief of pain. The two cases of small children (cases 10 and 11) in which the time for pain relief could not be accurately determined presented similar time relationships to those

of cases 1 to 9. The symptoms of acute pyelitis are well known to be frequently self limited, and the evaluation of a new therapeutic measure in this condition is difficult. It is apparent however, when the short interval between the exhibition of the solution and the relief of pain is compared with the relatively prolonged duration of symptoms prior to pituitary therapy, that our favorable results cannot logically be attributed to spontaneous remissions.

The remaining patients in this series (patients 12 to 16, inclusive) were ill for an average of only twenty hours before the exhibition of the solution and consequently in this group the customary methods of medical treatment were not given a fair trial. Patient 12 had had constant renal pain for twenty-four hours. This was not controlled by two full doses of morphine and atropine, but complete and permanent relief followed within one hour after the first dose of the solution. In cases 13 and 14, solution of pituitary was the only medication employed. The pain had lasted three and twenty-four hours respectively, and in both cases relief was obtained one hour after the solution of pituitary was given. Patients 15 and 16 had had pain for twenty-four hours. In both instances alkalis were simultaneously administered with the solution. Pain was permanently relieved in eight hours in case 15 and in case 16 temporary relief was obtained one hour after the first dose and permanent relief one hour after the second.

The striking relief of pain noted was in all cases associated with mitigation of such complaints as urinary frequency, dysuria and nausea.

Objective improvement was also apparent following the use of the solution. The fever was lowered in two days or less in cases 6, 11, 12, 15 and 16. Case 11 deserves emphasis.

A girl aged 3 years was in the hospital for eighty-four days and afforded well controlled observations during two acute attacks. She had been acutely ill for seven weeks before hospital entry and intensive medical treatment throughout this period had been of no avail. During the first eight days of hospitalization fluids and alkalis were forced without apparent benefit. On the eighth day the administration of solution of pituitary was added and the fever promptly subsided. Ten days later the solution was discontinued and the child remained symptom free for the following ten days. At this time a second acute attack occurred in spite of the continued forcing of fluids and alkalis. Two days after the onset of the second attack, solution of pituitary was again given, and the fever again promptly subsided. She remained symptom free for the remaining fifty-two days of her hospital stay.

Disappearance or diminution of the pathologic elements of the urine often paralleled the clinical improvement but was not a prominent feature of the therapeutic action of the solution.

Sufficient pharmacologic evidence is available to afford a rational basis for the use of systemically administered drugs to augment the tone and peristalsis of the renal pelvis and ureter in atonic conditions of these structures. Our experience is limited to solution of pituitary which acts directly on smooth muscle but it is quite possible that certain other drugs especially

the stimulants of parasympathetic innervation, may prove to be more efficient for this purpose.

It is not our intention to suggest that ureteral catheterization can always be advantageously supplanted by drug stimulation, but we are of the opinion that this method of accelerating drainage will prove useful in certain selected cases in which instrumental drainage is for some reason difficult or impossible. In our opinion, a course of pituitary therapy is logically a suitable follow-up measure to instrumental drainage.

In the cases of pyelitis secondary to definite organic obstruction to urinary drainage, the increased intrapelvic pressure induced by the solution of pituitary may increase the pain. This effect of the solution was observed by one of us in a case that was subsequently shown to present an almost complete organic ureteral stricture. Tschernjak⁸ has reported a similar experience with the solution in patients having ureteral stone.

Although the exhibition of solution of pituitary is simple and relatively safe certain contraindications may be noted. Recent experiments⁹ indicate that it causes

Clinical course in a girl aged 3 years

constriction of the coronary arteries. It is therefore contraindicated in the presence of coronary disease. Conditions in which it should be used with caution are myocardial weakness, hypertension, arteriosclerosis and pregnancy.

SUMMARY

1 Evidence from the literature establishes the fact that certain systemically administered drugs such as solution of pituitary, augment the tone and peristalsis of pelvic and ureteral musculature.

2 In sixteen cases of pyelitis renal pain of relatively prolonged duration was promptly relieved by solution of pituitary. The associated symptoms of fever, nausea, frequency and dysuria were also ameliorated, although in a less spectacular manner.

3 In our opinion these results are due to accelerated drainage of the upper urinary tract induced by the solution.

DERMATOMYOSITIS

REPORT OF CASE

JOHN C. McGARRAHAN, M.D.

COHOES, N. Y.

The comparative rarity of cases of myositis with associated neuritis, dermatitis or arthritis makes the report of individual cases seem advisable. Dermatomyositis has been well defined as "an acute subacute or chronic disease of unknown origin characterized generally by a gradual onset with vague and indefinite prodromata followed by edema, dermatitis and multiple muscle inflammation." The very rarity of the disease militates against an early diagnosis, especially since the symptoms are indefinite and common to frequently encountered entities.

It is agreed that the condition most readily confused with dermatomyositis is trichinosis, the absence of eosinophilia in the former being an important diagnostic point. However in this case eosinophilia was quite pronounced and has been frequently reported in similar cases. There is a pronounced difference in the usual onset of the two diseases, that of trichinosis tending to be fulminating, that of dermatomyositis tending to be insidious. In the majority of cases of dermatomyositis a history of shortly antecedent infection of the upper respiratory tract is obtained. The finding of trichina embryos in the blood, of course determines positively the nature of the disorder, as does a biopsy of affected muscle. Various bacteria have been found in the muscle tissue at biopsy, but not in every case. The finding of *B. coli*, staphylococcus, streptococcus and meningococcus has been reported. Unfortunately a biopsy was not permitted in this case.

There is, naturally, no specific treatment for dermatomyositis. Attention to the patient's general well being with a view to the development of a possibly specific resistance, is essential. The use of salicylates or their derivatives is one of the most frequently mentioned therapeutic measures, with some apparent comfort to the patient but with little effect on the underlying pathologic condition. Physical therapy in one or several of its forms has been freely used. No mention of the use of vaccine therapy has been found in the literature reviewed. That procedure seemed of enormous value in the case presented here, even though the nature of the infecting organism was proved only presumptively.

REPORT OF CASE

T. H. P., a white man, aged 23, a radio salesman, admitted to the Cohoes Hospital, Aug. 1, 1932, for observation, complained chiefly of aching of the joints, especially the knees, stiffness, and general malaise.

His was a premature birth, a seven months uterogestation. At 8 months and at 9 years he had had attacks of bronchopneumonia. Tonsillectomy was performed at 12 years. At the age of 10 years he began to put on excessive weight, at 17 years his weight reached 240 pounds (108.8 Kg.). He had measles and chickenpox and, at 12 years, an acute articular rheumatism. At 15 years he was treated for a skin condition accompanied by marked thickening and discoloration of the finger and toe nails thought to be glandular in origin. He had gradually lost weight to 200 pounds (90.7 Kg.) before the onset of the present illness.

In April, 1932, the patient had what was considered an influenzal type of infection. Following this attack he did not regain his strength and shortly noticed that his ankles were larger than normal. Walking was slightly painful. Later his wrists were painful. His temperature at this time ranged

slightly above 99 F. in the evening. No distinct pathologic condition was located and he was advised to have roentgenograms made of his teeth and sinuses. No evidence of a pathologic condition of the sinuses was determined, but three apical abscesses were located. The affected teeth were removed and the patient was put on salicylates with but little demonstrable effect. The patient went for a two weeks stay in the mountains, returning unrelieved. At this time the evening temperature reached 101 F. at times. On his return, the complaint of unproductiveness cough made a roentgenographic examination of his chest seem advisable. This showed no evidence of active pathologic changes. The patient was urged to consider hospitalization for study in view of his increasing fatigability, slightly increasing fever and the persistence of his arthritis. This he refused to do. He was referred to an internist for diagnosis and advice when a differential count revealed 31 per cent eosinophilic cells. In the meantime negative reports had been obtained from agglutination tests for typhoid, paratyphoid A and B and undulant fever. Urinalysis showed no evidence of a genitourinary infection. The consultant felt that the patient's condition was the aftermath of an influenzal infection and advised bed rest and salicylates. The patient finally consented to enter the hospital for rest and further study.

On admission to the hospital there was nothing remarkable in the physical examination except for the pallor of the patient's skin, the evidence of considerable recent loss of weight, palpable spleen and some thickening about the ankles and wrists with slight limitation of motion. The basal metabolic rate determined the day following admission, was normal.

On the evening of the fourth day after admission the patient suddenly noticed that the right side of his face and right arm were numb and he was unable to enunciate words clearly. Following this there developed a left frontal headache of a severity requiring morphine for relief. There was some weakness of the muscles of the right side of the face and the right arm. He vomited several times during the night. The following day these signs and symptoms slowly subsided. A blood culture taken that day was sterile. The attack was apparently allergic, secondary to an enterocolitis which cleared up in a few days.

The patient was given salicylates in moderate dosage 10 grains (0.65 Gm.) every four hours. The greatest relief was obtained by the use of local heat at the wrists and ankles, flannel bandages being used, with baking for three half hour periods daily.

The pulse and temperature were erratic, the evening temperature often reaching 99 F. rarely 100 and frequently remaining normal. The pulse rate ranged between 90 and 100. The respiratory rate was practically constant at 20.

During the first four weeks of hospitalization the patient gradually showed evidence of general improvement under the regimen of complete rest. During this period, however, it was noticed that the swelling about the wrists and ankles was becoming firmer. The skin was becoming glossy in small slightly elevated patches about one fourth inch in diameter some of which gradually became confluent. The patient complained of the gradual stiffening of his fingers and of a marked tremor when using his hands. The firmness of the forearm and leg muscles was then obvious with slightly increased firmness of the thigh and upper arm muscles. While active use of the involved muscles was not painful, stretching of the muscles was quite painful. The muscles were not tender to palpation. No involvement of muscles other than those of the extremities could be demonstrated. There was no evidence of nerve involvement and no change in the deep reflexes.

At this time biopsy to determine, possibly, the nature of the infecting organism was advised. Permission was refused for this. The teeth having been cared for and the tonsils out, it was felt that the offending organism was most probably to be found in the nasal passages or nasopharynx. Intradermal skin tests were made with a group of organisms found in association with respiratory infections on the theory that the patient might show a reaction to the organisms against which there was no systemic resistance. All tests were negative except for staphylococcus, which gave a pronounced local reaction. Three successive nasal cultures yielded pure growths of *Staphylococcus aureus* and from these an autogenous vaccine was made.

The administration of the vaccine was begun, September 24. By this time the skin of the dorsum of the hands and forearms and the dorsum of the feet, the lateral aspects of the ankles and the anterior surfaces of the legs had become firm, white and glossy. The skin was not tender and pitted but slightly. It was difficult to get the pulse in the radial or the dorsalis pedis arteries. The patient was complaining of some coldness and numbness of the hands and feet. There was a noticeable increase in the boggy firmness of the thigh and upper arm muscles. The temperature at this time rarely exceeded normal.

Two weeks after inauguration of the vaccine therapy there was a pronounced improvement in the condition of the proximal muscles of both upper and lower extremities with slight improvement in the distal muscle groups. The skin lesions were subsiding and, while still pale and glossy, were no longer raised.

The patient was sufficiently improved to be in a chair by the middle of October. At this stage the chief difficulty was due to the gradual contraction of the affected skin about the joints, with involvement of the underlying tendons. Palpation of the wrists yielded no sense of the normal feel of the periarticular structures, skin and tendons seemed almost a solidly agglutinated mass. The fingers could be flexed with difficulty. The ankles were almost inflexible.

By the middle of November the patient was taking a few steps around the room and two weeks later was able to walk by himself through the corridors. His gait was badly restricted by the condition of his ankles. He was discharged from the hospital, December 5.

The white count exceeded 7,000 cells per cubic millimeter only once. The percentage of eosinophilic cells presents an interesting picture:

July 19, 26 per cent
July 22, 29 per cent
August 1, complete bed rest
August 2, 18 per cent
August 5, 13 per cent
August 13, 14 per cent
August 29, 14 per cent
September 7, 17 per cent
September 24, vaccine begun
October 4, 11 per cent
October 26, 3 per cent
November 12, 5 per cent
November 23, 5 per cent

Since the patient left the hospital he has made slow but steady improvement in regaining the function of his hands and feet. Flexion of the hands progressed to the point at which he could handle his car even in heavy traffic with comparative ease. At the present time flexion of the fingers and thumb is just short of complete closure of the hand. The ankles have not recovered so well. The patient had long suffered from a moderate degree of pronation with some flattening of the longitudinal arches in both feet presumably as a result of his earlier excessive weight. Because of the location of the major amount of scar tissue at the outer aspects of the ankles, the foot fault was greatly aggravated. Some improvement has resulted from raising the entire inner border of both soles nearly three-eighths inch.

The areas of involved skin have softened materially and the anchoring of the tendons to the skin is much lessened. Particularly about the ankles, where the scars resemble closely those caused by third degree burns, the interference with skin nutrition by scar contraction has caused repeated cracking and peeling of the epidermis. Physical therapy has been discontinued because of the sensitiveness of these areas, and entire reliance is being placed on exercise to restore function so far as may be possible.

Muscle atrophy is present to some degree in the involved muscles but whether this is a primary result of the inflammatory process or is secondary to the involvement of the tendons in scar tissue is impossible to say. Since the thigh and upper arm muscles have become almost normal in consistency and volume and since there was no demonstrable involvement of periarticular structures at the knees or elbows, the presumption is that much of the atrophy is due to diminished activity.

CONCLUSION

The report covers the progress of a case of dermatomyositis with recovery. The outstanding features of the case are the preliminary influenzal type of cold, the low grade arthritis, the low grade febrile reaction, the eosinophilia, the inflammatory process in the muscles of the upper and lower extremities, the stiffening of the wrists, fingers and ankles with the involvement of the periarticular structures, the rash of slightly raised papules becoming confluent, the slow convalescence and the final difficulties due to scar contracture.

The return of the percentage of eosinophilic cells to within normal limits in approximately four weeks after the inauguration of treatment with an autogenous vaccine from the probable focus of infection, together with the pronounced clinical improvement in the same period suggests the possible value of this type of therapy in cases of dermatomyositis.

CONGENITAL ANOMALY OF THE OMENTUM CAUSING TORSION

REPORT OF A CASE

G. G. O'BRIEN, M.D.
CHICAGO

D'Errico¹ defined torsion as "a pathological displacement in which the involved structure becomes, in whole or in part, so twisted on itself as to produce strangulation of its tissue." Of the abdominal viscera, torsion of the intestine and appendix is comparatively common, and torsion of the omentum comes next in frequency.

The question of the etiology of torsion of the omentum has been discussed in the literature with many suggestions. Payr,² after experimental work in which he produced spontaneous torsion, finally concluded that torsion was due to hyperemia in the veins. Anatomic variations in the blood supply of the omentum have been considered a cause also. Baldwin³ expressed the belief that the etiologic factor was congenital formation of a pedicle, Draper⁴ that it was congenital omental bands, and Bierman and Jones⁵ that it was congenital accessory omentum. Inflammation, exaggeration of normal omental movements and increased peristalsis have also been suggested. German,⁶ of the Cambridge City Hospital, expressed the belief that the basic etiologic factors were thrombosis and embolism; that thrombosis could be caused by slight trauma to the delicate endothelium lining the omental veins, or an endoventis secondary to a focus of infection elsewhere, and that embolism could follow the thrombosis or come from some obscure source. Wakeley,⁷ however, believed that hernia is the most common cause of torsion of the omentum and that those occurring on the right side seem to be most frequent. Up to 1929, he could find only twenty-five cases, including two of his own in which the condition was unaccompanied by any form of hernia.

- 7 Wakeley, C. P. G. Torsion of the Great Omentum. *No. e. on Two Cases.* *M. Press.* 127: 38 (Jan. 9) 1929.

Cowell⁸ classified torsion of the omentum as (1) abdominal either primary without apparent cause or secondary in which it is associated with diseases of an abdominal or pelvic organ, and (2) hernial, intra-saccular, intra-abdominal or combined.

Primary torsion is commonly a progressive condition with a history of intermittent short attacks of cramp-like pains. There may be a history of attacks of nausea and vomiting of a constant type. According to Thorek,⁹ acute torsion may be ushered in with severe incapacitating pain in the upper or lower right quadrant of the abdomen suggestive of peritonitis. MacWhorter¹⁰ stated that the exquisite tenderness in the right side of the abdomen and the cramp-like pain produced by movement are the most characteristic symptoms, rigidity and muscular spasm may prevent palpation of a mass.

In the differential diagnosis, Jeffries¹¹ mentioned Henoch's purpura, intussusception, acute pancreatitis, enterospasm or organic intestinal obstruction, appendicitis and tuberculous peritonitis as some of the pitfalls. The chief points in the differential diagnosis as given by D Errico,¹² are as follows: 1. Nausea and vomiting which are usually present in acute appendicitis may both be lacking in torsion. 2. A mass if present develops suddenly with torsion and slowly with appendicitis and may be movable in torsion but is fixed in appendicitis. 3. Tenderness and spasm in the right lower quadrant are almost always present with appendicitis whereas in torsion the tenderness is less marked and more diffuse. If the possibility of torsion of the omentum is considered in the differential diagnosis, acute pain in the abdomen may suggest it. In torsion of the omentum the percussion is dull but in acute appendicitis it is resonant at first and the temperature is between 99 and 102 F, whereas in torsion of the omentum it is between 98 and 100 F, and leukocytes may increase from 9,000 to 17,000 in each cubic millimeter of blood.

In the hernial types of torsion, especially when a long standing painless scrotal type of hernia suddenly becomes irreducible, painful and enlarged and a rapidly developing mass above Poupart's ligament appears, Morris¹³ states that acute torsion of the combined hernial type should be suspected.

As far as the differential diagnosis is concerned, Thorek⁹ believes that it is of academic interest only, the significant thing being to recognize the presence of a grave condition in the abdomen which calls for surgical intervention. Radical removal of all the twisted portion of the omentum is the treatment of choice, he believes, because even if it is possible to untwist the torsion there is always a tendency for it to recur. D Errico¹² advocated care in handling the omentum because of the possibility of embolism and also that in resecting the omentum care should be exercised to ligate the pedicle in small sections to avoid kinking of the bowel. All investigators seem to agree that the prognosis is favorable.

REPORT OF CASE

A housewife aged 63 admitted to the South Shore Hospital with severe and lancinating pain on the right side of the abdomen about the level of the umbilical region, had been well until seven days previously when after a dinner of baked beans distress developed in the abdomen which the patient thought was gas. This disappeared and two days later she again ate baked beans and severe pain developed in the left upper quadrant of the abdomen. The next day since the pain continued she took a dose of magnesium sulphate. The following day, the pain moved to the lower right quadrant and a good bowel movement followed the dose of magnesium sulphate. She ate a hearty dinner. Later nausea developed during an automobile ride. As the nausea persisted the patient took castor oil and went to bed. The sixth day from the onset of symptoms she was up and around but the pain in the lower right quadrant was so severe that she returned to bed. The pain and nausea persisted, the bowels moved freely. The following morning the seventh day from the onset of the illness a physician was called and the patient was moved to the hospital.

The patient had had six children, four of whom were living and well, one had died following thyroidectomy and one from tuberculosis. The history of previous illnesses and the family history did not reveal anything of significance.

On admission to the hospital the patient who was well developed seemed to be acutely ill. The general examination revealed an injected pharynx but nothing abnormal in the thorax or cardiovascular system. The temperature was 98.6 F, the pulse rate was 90 beats a minute and the respiration rate was 20. The abdomen on which there was considerable fat was covered with striae gravidarum and was rigid, particularly on the right side, the muscles were flaccid. There was no pain or tenderness over the kidneys but in the region of the appendix the pain was severe. The urine was acid in reaction and contained numerous epithelial cells. Leukocytes numbered 12,800 in each cubic millimeter of blood of which 70 per cent were polymorphonuclears, 1 per cent eosinophils, 18 per cent small lymphocytes, 2 per cent large lymphocytes and 1 per cent transitional.

The preoperative diagnosis was acute appendicitis and operation was performed immediately. Under general anesthesia a right rectus incision about 12.5 cm long was made and the rectus muscle split. When the peritoneum was opened a bloody serum escaped. A tongue-shaped process of omentum extending from the right margin of the transverse colon, separate and distinct from the main body of the omentum was found. This tongue-shaped process which was dark and indurated was adherent to the anterior abdominal wall and to the intestine beneath. It was raised up and the adhesions between the small intestine and this portion of omentum were broken. This process of omentum was twisted on itself five times in a counterclockwise direction, was very dark and showed beginning gangrene. It was about 8 inches (20 cm) long, 3 inches (7.6 cm) wide and about 2 inches (5 cm) thick. It contained fresh blood within it but otherwise showed no significant abnormality on gross examination. It was crushed above the torsion, clamped and tied close to the transverse colon. No area of inflammation was found in the abdomen below the omentum. The main body of omentum was on the left side of the abdomen and was normal in appearance. Because of the danger of infection no further exploration of the abdomen was made. A split tube drain was inserted and the abdomen closed.

Sections through the hemorrhagic area revealed dilated blood spaces filled with fresh blood. The mesothelium was proliferating and there was slight infiltration of polymorphonuclear leukocytes at the surface. The postoperative diagnosis was torsion of the tongue-shaped anomalous process of omentum with acute hemorrhage into it and early inflammation.

The patient's convalescence was uneventful and she was dismissed from the hospital on the twelfth day after operation. Four days later on a follow-up visit to her home the patient was found to be up and around and in good condition.

Blood-stained fluid was encountered in this case when the peritoneal cavity was opened. This is at variance

with Black's¹⁴ case in which there was an absence of blood-stained fluid but like that of Cowell⁸ who stated that a rush of blood-stained fluid when the abdomen is opened should remind one of the possibility of torsion of the omentum. In Black's case, however, there was marked distention of the colon a form of reflex ileus due to irritation of the splanchnic nerves involved in the torsion.

The congenital anomaly, a tongue-shaped process, which was separate from the omentum, was probably the etiologic factor in the torsion. Bierman and Jones⁵ described two cases with an accessory omentum. Although torsion was not present in either of their cases the accessory omentum has been suggested as an etiologic factor by many authors.

ADENOMATOSIS COLI AND CARCINOMA OF THE COLON

REPORT OF CASE ILLUSTRATING MULTICENTRIC MALIGNANCY

JOSEPH FELSEN, M.D.

AND

JOSEPH J. WELLS, M.D.

NEW YORK

The purpose underlying the publication of this report is to point out certain pertinent observations relative to the development of multiple primary malignant tumors of the large bowel on the basis of adenomatous polyps. No attempt will be made to dispute the validity of Billroth's strict criteria with regard to multiple primary malignant tumors. It appears to be quite generally conceded that the simultaneous and independent development of carcinomas from two or more adenomatous polyps of the colon or rectum does occur. The evidence that has accumulated in support of this contention is too voluminous to permit of full presentation within the limited scope of this paper. The entire subject of multiple primary tumors has been extensively reviewed by Major,¹ Owen,² and Warren and Gates.³ The following case in which relevant data only are presented, is particularly instructive in that a benign adenomatous polyp and two stages in the development of a malignant growth from such a polyp are quite clearly shown.

REPORT OF CASE

Anamnesis—J. H., a man aged 44 admitted to the Bronx Hospital Jan. 23, 1932 complained chiefly of obstipation of four days' duration accompanied by cramplike pains near the umbilical region. These pains occurred irregularly and increased in severity during the twenty-four hours prior to admission possibly because he had taken several cathartics. There was no nausea or vomiting. Several enemas returned clear, and no flatus was passed.

There were two previous attacks of a similar nature, two and four months before both of which lasted only two days and were relieved by cathartics and enemas. Before the onset of these attacks the bowel movements had been fairly regular.

The patient had never noticed any blood in the stools. Two weeks prior to the present attack he complained of rectal tenesmus for the first time.

He had lost about 20 pounds (9 Kg.) during the past six months, which he attributed to voluntary restriction of diet.

Examination—Marked distention was present throughout the abdomen, especially on the right side. The distended cecum and ascending colon could readily be made out by palpation. The sigmoid could not be definitely outlined. No other masses could be felt. No hernial protrusions were present.

No masses could be felt in the rectum. The prostate was not enlarged.

Röntgen examination without the use of a contrast medium was made in both the prone and the erect position. This procedure demonstrated an enormous gaseous distention of the large intestine, which began at the cecum and ended abruptly in or just above the sigmoid colon. The erect position demonstrated fluid levels.

Operative Procedure and Result—Two hours after admission, a first stage cecostomy was performed under procaine hydrochloride infiltration anesthesia. Twenty-four hours later the cecostomy was completed by perforating the cecum with a cautery.

Twelve days later an exploratory laparotomy revealed a constricting tumor of the descending colon, about 3 inches below the splenic flexure. A few other scattered polypoid masses were felt proximal to this point. The splenic flexure and part of the transverse colon were resected.

Convalescence was uneventful, the patient being discharged from the hospital approximately one month after operation. At the time of discharge he was in excellent condition, with the wound on the left side healed and a very slight opening remaining on the right side.

Pathologic Report—A specimen submitted for examination consisted of a portion of colon 21 cm. in length. On the mucosal aspect just above the center of the specimen, there was a definite hour-glass constriction due to the presence of a round sessile, pinkish tumor mass that measured 6 by 4 cm. in its largest dimensions. The margin of this mass was sinuous, elevated, very much indurated and somewhat everted. The surface was moderately blood tinged and exhibited a dimpled or depressed ulcerated central area. The latter corresponded to the site of greatest constriction and was densely hard. Eight centimeters below this region was another sessile tumor, 2 by 3.5 cm. characterized by being somewhat mammillated without exhibiting any ulceration or necrosis but with a raised, rolling edge. The intervening mucosa appeared to be quite normal. Situated approximately 5 cm. above the large ulcerated tumor was an oval, somewhat papillary, solid dark red slightly pedunculated polyp measuring 1 by 1.2 cm. Four small, hard, shotty lymph nodes could be felt in the mesocolon and another larger node directly beneath the floor of the ulcerated area just described.

Microscopic examination revealed (1) large ulcerated mass, adenocarcinoma, grade 3, (2) smaller sessile mass, adenoma malignum, grade 1, (3) benign polypoid adenoma, (4) lymph nodes, inflammatory hyperplasia except for one epicolic node that exhibited possible very early involvement.

Follow Up—The patient was examined at intervals following discharge and one year later showed no evidence of recurring malignancy. The large intestine appeared to be functioning normally. There was no abdominal discomfort or bleeding by rectum, and the patient had gained considerable weight.

Tables 1 and 2 summarize quite briefly the general incidence of multiple malignant tumors and their relative frequency in the large intestine. It is interesting to note that double carcinomas occurring in the same organ are most frequent in the large intestine (55 out of 150 cases). The explanation lies quite clearly in the development of a malignant condition on the basis of multiple polypoid adenomas. It is with this phase of the subject that the remainder of the paper will be concerned.

The etiology of multiple polypoid adenomas is unknown. The earliest stages in their development have never been thoroughly studied for the simple reason that the patients are generally seen after the tumors have been definitely established. Ribbert⁴ attributes the origin of the polyps to misplaced embryonal cells of the intestine, while Verse⁵ concludes that they arise as a result of diffuse catarrhal inflammation of the normal mucosa. These divergent views are important, in that they concern subsequent malignant degenerative changes. Ribbert presupposes an invasive cancerous process that involves the polyp only in part rather than a primary change in the epithelial cells per se. Lockhart-Mummery and Dukes⁶ agree with Verse in that they have observed a diffuse hyper-

transverse colon which is the seat of multiple sessile and polypoid adenomas, a large arborescent papillary tumor and a diverticulum. It appears quite logical to assume, therefore, that knowledge regarding the origin of polyposis is incomplete.

In actual practice, the patient is seen with the tumors already visible in the gross. Though many authors, notably Schmeiden and Westhues⁸ and Fitzgibbon and Rankin,⁹ have classified polyps according to their gross

plasia of the mucous membrane followed by the development of multiple polypoid adenomas, and they regard this as an intermediate or precancerous stage. Lynch and Felsen⁷ have made similar observations but find it difficult to eliminate a fundamental underlying tendency to tumor formation, aside from any pre-existing inflammation. This is to say, the intestine exhibiting polyposis often appears to be peculiarly susceptible to other types of neoplasia or pathologic changes. For example, the last named authors have in their collection a resected portion of ascending and

characteristics and histogenesis it appears quite probable that these are all different stages in the development of the same tumor. One of us (Felsen) has been privileged to study a number of exquisite examples of what perhaps may be more properly termed "adenomatosis coli." All stages of development may often be discerned in a single specimen from the localized, pinhead areas of slight mucosal thickening

to the 5 to 10 mm sessile tumors and the larger polypoid adenomas. All three are different stages in the development of the same tumor. Sections taken from the earliest lesions exhibit merely a localized area of epithelial hyperplasia. As the process advances, a small flat visible tumor appears on the mucosa, grows progressively laterad and toward the lumen of the intes-

of the disease have been described. Briefly, it may be stated that the growth of the malignant tumor is relatively slow, depending of course on the degree of anaplasia. The process is limited for a long period by the submucosal lymphatic plexus. In general, it may be said that carcinomas in the colon are more highly anaplastic than those in the rectum and that with increasing anaplasia there is a tendency to earlier age incidence and greater radiosensitivity but a correspondingly poor prognosis with regard to duration of life.

The clinical features of adenomatosis coli and multiple primary malignancy of the colon deserve men-

tion. First, there is a definite familial tendency of the mendelian type,¹⁰ the disease being transmitted by both male and female. It affects both sexes. Second, there is a distinct tendency toward malignant degeneration. Doering¹¹ reports that, among thirty-six patients with polyposis, twenty-one died of intestinal carcinoma. The statistics covering this point are summarized in table 3.

Verse, Fitzgibbon and Rankin, Westhues and others are of the opinion that all carcinomas of the colon or

Fig 2—Section taken from A (fig 1) normal morphology of glands and uniform well distributed stroma

tine. When sufficiently large, projecting considerably above the level of the surrounding normal mucosa, the tumor serves as a foreign body that the intestine promptly attempts to dislodge. Owing to the fact that there is no fixation to the underlying layers of the large intestine, the process being confined to the mucosa, and because of the loose mucosal stroma, the tumor gradually acquires a pedicle of mucous membrane. This pedicle is often of considerable length but maintains a satisfactory vascular supply for the tumor, which may be seen sitting on the apex of a conical stem of mucous membrane.

The subsequent course of these tumors is a dubious one. In a given case, the majority or all may remain perfectly benign throughout life. In a certain number, however, one or more of the adenomas sooner or later undergo malignant change. The earliest gross indication is a fixation to the underlying and surrounding intestinal wall. A slightly pedunculated oval or round tumor becomes sessile and flattened, increases its surface area and often exhibits a central dimpling or slight necrosis. The latter is probably due to the inability of the vascular supply in the connective tissue stroma to keep up with the relatively rapid growth. Sections show elongation and distortion of the glands and active proliferation, so that the epithelial lining becomes multilayered. The stroma is papillary and well vascularized. Disturbances in cell morphology, loss of polarity, hyperchromatism and elongation of the nuclear substance supervene. The normal, well differentiated glandular tubule, consisting of a single layer of columnar cells resting on a basement membrane is gradually replaced by a dedifferentiated anaplastic carcinoma. Conditions determining the further progress

Fig 3—Section taken from B (fig 1) bizarre glands which are beginning to penetrate deeper structures and poorly balanced stroma at this stage the tumor is capable of producing metastases

of the rectum originate in polyps. Lynch and Felsen are inclined to this view but are not willing to accept such an origin in every instance.

The feature of multiple primary carcinomas exhibited in our case is of great interest because of its relatively

10 Norbury L E C Proc Roy Soc Med 24 198 (Dec) 1930

frequent occurrence in connection with adenomatosis coli¹² and its relative rarity in most other organs. The multicentric origin of certain carcinomas was first established by the studies of Peterson¹³ and Hauser¹⁴. The striking frequency of such an occurrence in multiple polyposis of the gastro-intestinal tract was pointed out by Ribbert,¹⁵ who collected thirty cases. The theo-

SUMMARY

1 The case reported here admirably illustrates the transition stages from adenoma to carcinoma.

2 Accumulated data point to an underlying tendency to neoplasia in adenomatosis coli.

3 Because of the high incidence of malignant degeneration in adenomatous polyps, their removal at an early stage is important. When removal is impossible because of their number, careful periodic examinations by means of the contrast enema and sigmoidoscope are indicated.

4 When malignancy supervenes, local resection results in a high percentage of cures.

Clinical Notes, Suggestions and New Instruments

SARCOMA AND TUBERCULOSIS OF THE STOMACH

CALVIN B. RENTSCHLER, M.D. AND RICHARD C. TRAVIS, M.D.
READING, PA.

Associates in Surgery and in Roentgenology, respectively, at the Reading Hospital.

The combination of sarcoma and tuberculosis of the stomach is a unique condition.

Sarcoma alone is a comparatively unusual form of neoplasm arising from the stomach wall. Ewing¹ estimates that sarcomas constitute 1 per cent of all stomach tumors. In his review of cases in 1920 Haggard² found that 244 cases had been reported of which 107 came to operation, the diagnosis in the remainder having been made post mortem. Balfour³ and

Fig 1—Appearance before operation.

McCann made a clinical analysis of the fifty-four cases of sarcoma of the stomach that have been studied at the Mayo Clinic from January 1908 to July 1929, inclusive.

2 Haggard W. D. Sarcoma of the Stomach with Report of a Case and an Analysis of 107 Cases Operated on. Surg. Gynec. & Obst. 31 505 (Nov) 1920.

3 Balfour D. C. Surg. Gynec. & Obst. 50 948 (June) 1930.

Tuberculosis of the stomach is also comparatively infrequent. In 1917, Broders⁴ published a report of a case of tuberculosis of the stomach in a patient who underwent surgical treatment. He included an analysis of the cases reported until then and classified them as positive, probable, doubtful and rejected. There were forty-nine positive and 118 probable cases. Accord-

large amounts of mucus were obtained. Rest in bed seemed to help her a great deal and she was well for five years. Then, seventeen years before, she began to suffer pain in the epigastrium immediately after taking food, regardless of the quantity or quality. At this time the pain was relieved by buttermilk and alkali. Following this she was well until November 1932, at which time she contracted a severe cold in the chest. Medication given seemed to irritate the stomach, and she was unable to retain solid food. From this time on she quickly developed vomiting with excessive bloating immediately after the taking of even small quantities of any solid food. There was a continual sense of fullness with a dull ache between the shoulders during the attacks of vomiting. She had lost 20 pounds (9 Kg.) since the onset of her present illness. The patient believed that occasionally dark blood was seen in the stools. For the past two weeks she had been able to take nothing but clear liquids. Otherwise, there were no symptoms or complaints referable to the other systems nor to the special senses. She had been married at 27, her husband and one daughter, aged 32, were living and well.

Fig. 2—Lymphosarcoma reduced from a photomicrograph with a magnification of 260 diameters

Fig. 3—A field from figure 2 under high power reduced from a photomicrograph with a magnification of 560 diameters

ing to the classification that Broders employed in his paper, Good⁵ in 1931 reviewed thirty-three additional reports of cases from the literature and added two more cases. Two of these thirty-five cases were regarded as positive and twenty-four as probable. The remaining nine cases were excluded because they fell into the doubtful or rejected group or because surgical treatment was not employed.

The extreme infrequency of carcinoma and tuberculosis of the stomach is brought out by the fact that Sprunt⁶ in 1930 found only thirteen cases reported in the literature and added one of his own.

REPORT OF CASE

History—Mrs. E. M. M., aged 65, admitted to the Reading Hospital, June 4, 1933, complained of epigastric distress and vomiting after meals. She stated that twenty-two years before she had been in the American Stomach Hospital for catarrhal gastritis at which time she was treated by gastric lavage, and

Fig. 4—Tuberculosis reduced from a photomicrograph with a magnification of 170 diameters

Fig. 5—A field from figure 4 under high power reduced from a photomicrograph with a magnification of 560 diameters

Examination—The patient was slender, quite active and happy. She weighed 100 pounds (45.4 Kg.), the blood pressure was 120 systolic, 70 diastolic, the temperature, 98 F., the pulse, 72, and the respiration rate 18. The teeth had all been removed, and upper as well as lower dentures were in use.

⁶ Sprunt D. H. *Surg. Gynec. & Obst.* 51: 245 (Aug.) 1930.

The chest was of a long flat type. Expansion was limited and was equal and regular. The supraclavicular fossae were deep, and the substernal angle was acute. Tactile fremitus and vocal resonance were unaltered, and the percussion note was resonant. Breath sounds were harsh and vesicular. There were no definite rales nor other adventitious sounds. The apex beat was in the fifth interspace at the midclavicular line. The first sound was considerably slurred and of poor quality. The

Fig 6—Appearance after operation

rhythm was regular and the rate normal. There was no increase in cardiac dullness nor demonstrable murmurs. The abdomen was flat and symmetrical. There was a sense of diffuse resistance in the epigastrium with tenderness on deep palpation.

The urine was normal. A complete blood count showed hemoglobin, 66 per cent, red blood cells, 3,650,000, white blood cells, 4,900, color index, 0.9 plus, polymorphonuclears, 60 per cent, small mononuclears, 39 per cent, and basophils, 1 per cent. The blood Wassermann test was negative. Roentgenologic study of the thorax gave negative results on two occasions.

The roentgenologic examination of the

stomach (fig 1) revealed a large filling defect on both greater and lesser curvatures in the middle third. The contour of the defect did not have the appearance truly characteristic of carcinoma, however, the results were interpreted as indicating a malignant lesion that probably was carcinoma. There was 85 per cent retention at the end of five hours. From the roentgenologic standpoint, the lesion was deemed operable.

Operation—Exploration was advised and was done, June 5. Under spinal anesthesia a high right rectus incision, a little to the right of the midline, was made. The stomach appeared markedly shrunken and was empty. The stomach wall was firm and had irregular masses with complete obstruction, as it seemed. There were several of these masses in the lower and middle as well as lower part of the upper third of the stomach. A diagnosis of carcinoma was made. The glands along both curvatures of the stomach were markedly enlarged, the largest being the size of a walnut. The largest mass in the stomach wall seemed the size of a chicken egg. The gallbladder and liver appeared normal. The uterus and adnexa were small and atrophic. The appendix was small and normal and was not disturbed. A posterior Polya resection of the stomach, removing a little more than two thirds of the stomach as well as the glands along both curvatures, was performed. The abdomen was closed in layers.

Pathologic Examination—Macroscopic. The specimen consisted of a section of stomach measuring 12.5 by 4 by 3.5 cm and weighing 70.4 Gm. Embedded in the mesentery on both curvatures of the stomach section there were numerous firm round masses, the largest 2.3 cm in diameter. The stomach was firm and nodular, and, on sectioning the nodular areas offered increased resistance. At the middle portion of the specimen there was marked stenosis. The mucosa of the stomach was soft and edematous in some places, and in other places especially around the stenosed area, the mucosa was entirely ulcerated.

Microscopic. There seemed to be two distinct pictures, one in which there were a number of areas in which lymphosarcoma predominated (figs 2 and 3). If these areas had stood alone the diagnosis would have been pure lymphosarcoma. Then there were remains of smooth muscle in the wall of the stomach, areas of increased eosin-staining stroma, areas of coagulation necrosis, areas of giant cells, and even tubercles, a picture of tuberculosis (figs 4 and 5). Acid fast stains of the tissue failed to show tubercle bacilli.

The diagnosis of lymphosarcoma and tuberculosis was confirmed by A. C. Broders and Joseph Colt Bloodgood.

Postoperative Course—The postoperative convalescence was entirely uneventful. On the third morning the temperature and pulse both rose to 100 and promptly dropped to normal and stayed there. There was no postoperative vomiting nor gastric lavage. The wound healed by primary intention. The patient was out of bed on the twelfth day and left the hospital on the seventeenth day.

Since she left the hospital, convalescence has continued uneventfully. She is gaining in strength and weight. A postoperative roentgenologic check-up examination five weeks after operation (fig 6) revealed normal filling of the remaining portion of the stomach, with immediate emptying through the stomach. The stomach was completely empty in two and one half hours. No upper intestinal delay was found.

230 North Fifth Street

NECROBACILLOSIS OF THE LUNG

I. W. SHAW, M.D. AND I. A. BIGGER, M.D. RICHMOND, VA.

Necrobacillosis is an acute infectious disease due to *Actinomyces necrophorus* and is characterized by a coagulation necrosis followed by caseation. Infection of the lung by *Actinomyces necrophorus* has been reported but once. This was by Cunningham,¹ and the organism was isolated from the lung abscess at necropsy.

The case reported here is of special interest because of the fact that the organism was isolated from the living patient and also because of the apparent rarity of necrobacillosis of the lung in human beings.

REPORT OF CASE

J. S., a Negro, aged 38, admitted to the St. Philip Hospital, Nov. 11, 1932, complained of a cough, expectoration of a large amount of foul sputum, weakness and loss of appetite. The patient dated the onset of his illness to the latter part of August, 1932, at which time he was working as a gardener in New Hampshire. An infection of the upper respiratory tract developed and a few days later a productive cough, which became progressively worse. Two weeks after the

onset of symptoms a severe pain developed in the midclavicular region of the left side of the patient's chest, and a diagnosis of pneumonia was made. About the middle of October, approximately six weeks after the beginning of his illness a roentgen examination was

Fig 1—Appearance of the chest before operation showing a large cavity partially filled with fluid and extending up to the level of the lower border of the second rib in front.

From the Departments of Bacteriology and Parasitology and of Surgery respectively of the Medical College of Virginia.
1. Cunningham, J. S. Human Infection with *Actinomyces Necrophorus*, Arch. Path. 9: 843 (April) 1930.

made of the chest and he was told that he had pus in the left pleural cavity and was advised to have it drained, whereupon he returned to his home in Virginia. His family physician aspirated a small quantity of foul pus from the left side of the chest and referred him to a local hospital, where another roentgen examination showed a large cavity containing both air and fluid, involving the greater portion of the lower lobe of the left lung. The sixth rib was resected between the

Fig 2—Appearance of chest with the patient lying on his right side showing a large cavity with fluid level

anterior and posterior axillary lines, the parietal pleura was incised, and the interlobar septum and a part of both lobes of the left lung were exposed. There were numerous adhesions between the two layers of pleura but when some of these adhesions were separated a portion of both lobes of the left lung could be visualized. The upper lobe appeared normal but the lower lobe was dark and indurated. An aspirating needle was inserted into the lower lobe and thick foul pus was obtained. The wound was then packed with gauze and the patient sent to the St Philip Hospital for an operation for lung abscess.

At the time of his admission the temperature was 102 F and the pulse rate was 125 a minute. He had a distressing cough and a moderate degree of dyspnea. Because of the recent surgical incision, examination of the left side of the chest was unsatisfactory and the right side showed nothing of significance. Laboratory examination revealed urine, normal except for a trace of albumin, blood red cells 3 800 000, hemoglobin 80 per cent, white cells 17 700, polymorphonuclear leukocytes 88 per cent, lymphocytes 12 per cent. The Wassermann reaction was negative. Roentgenograms showed the right lung to be clear, while the greater portion of the lower lobe of the left lung was occupied by a large cavity.

November 14 three days after admission, the incision was reopened and the gauze packing removed, a segment about 4 inches in length was excised from the midportion of the seventh rib and an additional segment of from 1½ to 2 inches removed from the posterior segment of the sixth rib. An aspirating needle was inserted into the lower lobe of the left lung and thick pus obtained, so a cautery was inserted and a very large relatively smooth-walled abscess cavity was entered. An opening about 6 cm in diameter was made by excising a portion of the lateral wall of the abscess cavity with the cautery. This tissue was sent to the laboratory for diagnosis. The cavity was found to be about three fourths filled with thick cream-looking pus with an odor that was peculiarly pungent and disagreeable. Approximately 500 cc of this pus was aspirated.

Stained smears of this pus showed coccoid forms, rods and thread-like filaments. The longer forms presented a beaded appearance. Capsules were present. The organism was gram negative.

The cultures were prepared for aerobic and anaerobic growth. There was no growth under aerobic conditions. Cultures in the anaerobic shake cultures on the third day showed the colonies to be cottony with dark centers.

This micro-organism was classified as *Actinomyces necrophorus*. It varies in length from micrococci to filaments of more than 100 microns and in width from 0.75 to 1.5 microns. Some of the filaments have one clubbed extremity and the other tapering, while some show irregular thickening at the points at which the filament takes the stain heavily. In general, the filaments present the appearance of a chain of micrococci in a sheath, but when irregular staining takes place the round bodies take on a club shape. Again, the coccus-like bodies may be alternately arranged along the sides of the tubes. Some of the rods take the stain throughout, others at both ends, while some are beaded.

The cultivation of *Actinomyces necrophorus* is rather discouraging at times, as it is a strict anaerobe.²

Microscopic examination of the tissue removed at the time of operation was reported by Dr Lewis C Pusch as follows: "Collapsed pulmonary substance with perivascular and peribronchial fibrosis bordered on one side by dense fibrous granulation tissue infiltrated with leukocytes and histiocytes and having a surface composed of necrotic debris. There is no evidence of a specific infection. Diagnosis: wall of chronic pulmonary abscess."

Two weeks after operation, November 28, the left diaphragm was paralyzed by section of the left phrenic nerve. Following this, the cavity decreased in size rather rapidly, so that by December 21 there was little more than a large sinus leading into the midportion of the lower lobe of the left lung. A rubber drainage tube was inserted to prevent closure of the outside opening, and the patient was discharged from the hospital to his family physician.

Following operation the patient was given potassium iodide in increasing doses for about six months with only two short intermissions, which were necessary because of the appearance of a diffuse rash. The dose reached was 150 minims (9 cc) daily. Four roentgen treatments were given over the lower portion of the left side of the chest, Dec 1, 5 and 16, 1932, and on Jan 23, 1933.

January 23 the patient's general condition was greatly improved, but he still had a deep sinus, which obviously communicated with a bronchus. He was reexamined, April 21, at

which time it was found that the sinus still communicated with a bronchus, he was expectorating a small amount of pus. It was therefore decided that it would be wise to cauterize the walls of the sinus, and under local anesthesia a portion of the old scar was excised and the sinus tract thoroughly cauterized throughout its entire extent and packed with dry gauze. Following this procedure the patient's improvement was continuous and the sinus finally completely closed about September 1. The patient is now entirely symptom free, and roentgen examination shows only

Fig 3—Appearance of chest, Sept 20 1933 approximately ten months after operation. The left diaphragm is elevated and there is still a considerable excess of scar tissue in the left lower lobe. The patient at this time was entirely symptom free and the sinus completely healed.

a small area of relatively dense scar in the lower portion of the left lung and a moderate elevation of the left diaphragm, which is fixed to the lateral chest wall.

OBSTRUCTIVE HYDROCEPHALUS DURING COURSE OF CEREBROSPINAL FEVER CURED BY VENTRICULAR PUNCTURE AND INTRAVENTRICULAR INSTILLATION OF SERUM

ARTHUR J. ANTENUCCI, M.D., AND SEATON SAILER, M.D.
NEW YORK

Obstructive hydrocephalus occurring during the course of meningococcal meningitis is quite unusual today with the present methods of diagnosis and treatment. Rarer still is a favorable outcome when such a condition supervenes. In such a case one has to deal with a closed infection of the cerebral ventricles—an ependymitis or a pyocephaly—and the logical course would seem to be to puncture the ventricles, relieve pressure and administer specific serum. Signs of cerebral compression, stupor, increased headache and choked disk, may occur with considerable abruptness in the course of an infection that has seemed to be progressing favorably, and not infrequently late in the disease. Cushing and Sladen¹ in 1908 reported such a case in an infant, aged 6 months, long after the primary infection, and in whom meningococci were demon-

strated in the corpus callosum, thereby obtaining prolonged drainage. This method would seem to be preferable to puncture with a trocar which gives temporary relief and often must be repeated. Cazamian² employed the orbitosphenoidal route, practiced by Biet, for the injection of arsphenamine in dementia paralytica. In place of trephining and drainage, Herrick recommends Cobb's method of breaking down adhesions around the foramen

Fig. 1—Anteroposterior view showing anterior horns of both lateral ventricles well filled with air. The temporal horn does not visualize on the right side.

strated in the ventricular fluid, while the spinal fluid was found to be sterile. After repeated ventricular tapping and intra-ventricular administration of antimeningococcus serum, the infant appeared to be doing decidedly better, and tapping was discontinued. The infant died however some time later after exhibiting cyanosis and Cheyne-Stokes breathing.

In an infant the pressure effects may be warded off through the possibility of cranial enlargement.

The operation of ventricular puncture and administration of serum by the ventricular route was first performed by Cushing and Sladen in 1908. In infants, before the closure of the anterior fontanel, the procedure is relatively simple. Eleven cases with five cures were reported by Marchand. In adults the procedure is more formidable but still not too difficult. In thirty-two collected cases there were five cures. In any event, difficult though it may be, the procedure should be tried as a last resort in a condition that would otherwise be hopeless. Stetten and Roberts advise making a wide opening in the

Fig. 2—Stereoscopic view showing dilated right lateral ventricle with foramen of Monro and third ventricle well outlined. Small amount of air in left lateral ventricle above foramen of Monro.

corpus callosum and the fourth ventricle by manipulation of the head under anesthesia. Rolleston suggests that this method might cause dangerous traction on the vagus roots. The method appears to be often successful in causing a flow of cerebro-

Fig. 3—Posteroanterior view. Posterior and temporal horn of right lateral ventricle not visualized.

spinal fluid and, in one instance, brought back respirations after they had stopped.

The case to be presented is an exceedingly interesting one. A presumptive diagnosis of meningococcal meningitis was made on admission, on the basis of the clinical observations and the finding of cloudy spinal fluid. Treatment was started

From the Roosevelt Hospital.

immediately, and in a short while improvement was manifest. This was interrupted, however, by a complicating obstructive hydrocephalus, which was treated by ventricular puncture and intraventricular instillation of serum. This had to be repeated, but the patient's recovery was practically complete, despite complicating *Staphylococcus aureus* infection of the skin, and later herpes zoster.

REPORT OF CASE

A white woman, aged 29, married, was admitted, June 20, 1932, to the service of the late Dr Rolfe Flovd, in a semicomatose condition. A history was obtained from her mother. June 24, the patient had come home from work feeling cold and feverish. In the ensuing days, although under a physician's care, she became rapidly worse, severe headache and drowsiness developing. On clinical examination the following positive observations were made. The patient was acutely ill, with a temperature of 101.3 F, pulse 90, and respiration 20. She lay in bed, motionless, occasionally moaning. The skin was hot and moist, but there was no rash. Marked photophobia was present. The neck was stiff and the throat red. A bilateral Kernig sign was present. Otherwise the examination was not remarkable.

The laboratory data revealed spinal fluid, cloudy, under slightly increased pressure, cell count of 792 per cubic millimeter, polymorphonuclears, 100 per cent. A smear showed gram-negative intracellular diplococci. A culture was positive for meningococci. The spinal fluid sugar was 21 mg per hundred cubic centimeters. Hemoglobin was 78 per cent (Sahli), red blood cells numbered 4,190,000, white blood cells, 20,000, with polymorphonuclear neutrophils, 88 per cent, and lymphocytes, 12 per cent. The urine was turbid, straw colored and neutral, with sugar, 4 plus, no albumin, an occasional white blood cell, no acetone or diacetic acid and no casts or red blood cells.

Treatment was begun immediately on withdrawal from the spine of cloudy spinal fluid. Fifteen cubic centimeters of anti-meningococcus serum was given intrathecally every twelve hours, after a slightly larger amount of spinal fluid had been withdrawn. The patient did well during the week after admission. June 27, seven days after admission, the temperature dropped to normal. She appeared bright, cheerful and talkative, she said she felt much better. The signs were unchanged. One sterile culture had been obtained from the spinal fluid prior to this, and the culture of fluid removed on the 27th was later found to be sterile. The sugar had increased to 106 mg per hundred cubic centimeters. The cell count, after soaring from 15,000 to 30,000, came down to 7,000.

June 28, the patient appeared well. Examination of the fundi revealed that the vessels were distended in and around the disks. The disks were not sharp. The temperature stayed normal for about a week, and on July 10 it began to rise. At this time examination of the fundi revealed definite fullness of the vessels and haziness of the disk margins. There was no definite choking of the disks. The temperature continued for about a week, ranging between 100 and 102 F. The patient, however, felt quite well. Up to this time six sterile cultures had been obtained in the spinal fluid.

The patient's general condition was good. The temperature dropped to normal and stayed down for two days. On July 24 the temperature began to rise again. During this period she became definitely worse. It was the general impression in view of the sterile cultures, that the active process had subsided but spinal drainage was continued on the advice of our consultant neurologist, Dr Charles McKendree because of the temperature. The temperature remained elevated until August 3. Next day it came down, but the patient appeared drowsy and disoriented. She lay in bed perfectly still with staring eyes. The pupils were unequal, with the right one greater than the left. They reacted to light, the disks were choked. There was generalized increase of the deep reflexes. The patient was generally in a hypertonic state. A provisional diagnosis of ventricular block with internal hydrocephalus was made. The temperature began to go up, August 8. The condition of the patient was the same. The signs were definitely those of localization of the process with internal hydrocephalus. Ven-

tricular puncture with administration of serum into the ventricles was considered. This procedure was carried out by Dr Howard Patterson, August 13, as follows.

Incision was made into the scalp, after infiltration with procaine hydrochloride, 1 per cent at a point 2 cm to the right of the external occipital protuberance and 6.5 cm anterior to it. The skull was opened with a hand drill. A needle was inserted into the lateral ventricle, which was encountered about 4.5 cm from the surface of the brain. Fifteen cubic centimeters of clear fluid was obtained under slightly increased pressure. A syringe was applied and 15 cc of fluid, definitely less clear than the first specimen, was obtained. About 55 cc of fluid in all was removed. Fifteen cubic centimeters of anti-meningococcus serum was instilled and from 15 to 20 cc of air was allowed to run in. A roentgenogram of the skull was then made. The ventriculograms showed the following.

The left lateral ventricle was dilated and the right lateral ventricle was incompletely filled. The third ventricle and the foramen of Monro were well outlined and showed dilatation. The fourth ventricle was well outlined in a 45 degree angle film.

Fluid removed for culture was sterile. A smear showed a few polymorphonuclear cells, lymphocytes, and rarely a gram-negative intracellular diplococcus.

The temperature went down immediately after the procedure. The patient appeared definitely better. The mentality cleared. The soft tissues over the site where the lumbar punctures were made was by this time quite sore. The skin was macerated and inflamed. Up to this time the patient had had about fifty lumbar punctures.

August 20, a spinal puncture was performed. The fluid obtained was fairly clear. It was sterile. A smear showed a few pus cells. There were no organisms. August 26, the spine was drained again. Meningococci were found on culture. *Staphylococcus aureus* was also present. This was believed to be a contamination from the skin lesions. August 27, meningococci and *Staphylococcus aureus* were again found. There were 432 cells per cubic millimeter with 16 per cent polymorphonuclears. August 29, the spine was drained again and serum was administered in a slightly smaller amount than the amount of fluid withdrawn. The fluid, as reported later, contained meningococci and also *Staphylococcus aureus*.

The patient's general condition was much improved for about ten days after the ventricular puncture, in spite of the finding of meningococci in the spinal fluid. August 28, however, the temperature began to rise. Slowly stupor developed, the patient moaned continuously. The pupils were small, twitches were observed in the muscles of the upper extremities. Ventricular puncture was repeated, August 30 and 50 cc of clear fluid was removed under markedly increased pressure. No serum was given. The temperature went down immediately after the procedure. The next day she appeared in a very reduced state, her mentality was confused. The case from all appearances seemed hopeless. September 2, spinal puncture was done and serum given. Culture of this fluid later yielded *Staphylococcus aureus*, but no organisms were found on smear. It was considered wise at this time to discontinue lumbar punctures. From this time on, slowly but definitely, improvement was noted.

The patient had an uneventful course for the remainder of the period in the hospital, except for troublesome pain in the back over the site of the previous lumbar punctures. Herpes zoster also developed over the left side of the chest and the left flank. At the time of discharge, November 30, she appeared very well, although somewhat undernourished. The only residual signs demonstrable were inequality of the knee jerks the left being more active than the right, and a left patellar clonus.

We present this as a case of obstructive hydrocephalus occurring insidiously during the course of a meningococcal meningitis, at a time when it was generally believed that the patient was getting better. At no time was there difficulty in obtaining fluid by the lumbar route. After two ventricular punctures with administration of serum into the patient's ventricles the patient went on to recovery.

Council on Pharmacy and Chemistry

PRELIMINARY REPORT OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING
REPORT
PAUL NICHOLAS LEECH Secretary

PERTUSSIS VACCINE

(Eli Lilly & Co., After Method of
Dr Louis W Sauer)

All vaccines of B pertussis were omitted from New and Nonofficial Remedies in 1931. In the twenty years that had then elapsed since the first use of such a vaccine, no conclusive evidence had been accumulated regarding the therapeutic or prophylactic efficacy of such preparations. The Council held, therefore, that it was not warranted in retaining pertussis vaccines in New and Nonofficial Remedies.

The recent work of Dr Louis W Sauer (THE JOURNAL, Jan 28, 1933, p 239, and Nov 4, 1933, p 1449) has aroused renewed interest in the subject. Sauer states that preparations made according to his technic are valuable immunizing agents against whooping cough. Eli Lilly & Co is now manufacturing pertussis vaccine according to the Sauer method.

The Bordet Gengou bacilli are isolated by the cough plate method and cultured for forty-eight hours on the original Bordet human blood medium. Only the most hemolytic strains are used. The harvest is then scraped off into 0.5 per cent phenolized physiological NaCl and placed in a refrigerator for one week. This bacterial suspension is vigorously shaken daily during this time and is then cultured once daily for three days to insure sterility. The product is diluted to an approximate concentration of 10 billion bacilli per cubic centimeter. The dose used for all cases has been 1.0 cc injected into each deltoid followed in one week by 1.5 cc injected into each biceps and followed the next week by the injection of 1.5 cc in each triceps. Thus a total of about 80 billion killed bacilli are injected.

Using this method, Dr Sauer reported the inoculation of 394 children against whooping cough in the past five years. Twenty-nine were from families having one or more other children. 31 of whom were left uninoculated, as controls. All 31 of the controls contracted pertussis within three months to four years, while their inoculated brothers and sisters lived with them throughout the incubation, catarrhal and paroxysmal stages without contracting the disease. Of the remainder of the original 394, 162 were reported to have been definitely exposed to the disease, yet none contracted it. Sauer has thus presented 394 cases of apparent immunity (beginning three months after inoculation and extending to, and possibly beyond, four years following inoculation) to whooping cough under circumstances ordinarily considered conducive to the spread of the disease.

Although the earlier investigators tried to establish the value of pertussis vaccines in therapy, they came to the conclusion that, if such preparations were of any utility whatever, it was in prophylaxis. Accordingly, commercial vaccines have been used for many years in attempts to produce immunity, but, as the Council pointed out in 1930, with inconclusive results. The total dosage used in these earlier attempts rarely was over 20 billion bacilli; the material was injected in small individual doses over a protracted period of time, and the vaccines were made, as a rule, by subculture from stock cultures of variable age.

Sauer attributes his results in the face of the indeterminate results of the past, to the two chief points of difference in his work.

- 1 The use of only freshly isolated, highly hemolytic organisms in making the vaccine
- 2 The use of heavy doses of vaccine

It is well known that most organisms progressively lose their pathogenicity on repeated transplantation in vitro and recover it only on passage through a susceptible animal. This may have some bearing on point 1.

Concerning point 2, since the disease itself does not ordinarily manifest a profound toxemia, it might be expected that larger doses of the organism would be necessary to produce a reaction.

Although Sauer's work appears promising it is pointed out that the present series of cases is quite limited; the work has

been carried on in one locality (where, conceivably, the vaccines used may all have been of the same strain as the current infections), and the past results have been directly contradictory. In view of this the Council does not feel justified, at this time, in recognizing the use of pertussis vaccine of any sort for therapy or prophylaxis until more convincing evidence becomes available. The Council, therefore, postponed consideration of B pertussis vaccine, Lilly (Sauer method) to await the development of further evidence.

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COMMITTEE ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION FOLLOWING ANY NECESSARY CORRECTIONS OF THE LABELS AND ADVERTISING TO CONFORM TO THE RULES AND REGULATIONS. THESE PRODUCTS ARE APPROVED FOR ADVERTISING IN THE PUBLICATIONS OF THE AMERICAN MEDICAL ASSOCIATION AND FOR GENERAL PROMOTION TO THE PUBLIC. THEY WILL BE INCLUDED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED BY THE AMERICAN MEDICAL ASSOCIATION. RAYMOND HERTWIG Secretary

VAN CAMP'S PURÉED TOMATOES (ADDED SALT)

Manufacturer—Van Camp's, Inc., Indianapolis

Description—Pasteurized sieved tomatoes, seasoned with salt, largely retaining the natural vitamins and minerals.

Manufacture—Sound tomatoes at their height of color and flavor are washed in troughs of running water, rolled through reel washers equipped with water sprays for thorough rinsing, sorted and trimmed on continuous belts, and the underripe and overripe fruit eliminated. The selected clean tomatoes are sliced, passed through a preheating chamber containing an atmosphere of steam, the pulp is strained out in an atmosphere of steam and is passed over a screen permitting the passage of sieved material of desired fineness and texture. The sieved tomatoes are homogenized by being forced through small apertures into the sieved material itself to avoid incorporation of air, are salted in tanks containing an atmosphere of steam, 'vacuumized' by exposure in thin sheets to 'high vacuum,' filled into enamel lined cans, and pasteurized for a definite period. Precautions are taken to avoid incorporation of air during the entire operation to minimize vitamin destruction.

Analysis (submitted by manufacturer) —	per cent

Vitamins—Careful selection of vine ripened tomatoes, vacuumizing to remove air naturally in the tomatoes, the exclusion of air throughout the preparation and processing of the juice, insure a high retention of the natural vitamins. An excellent source of vitamin C and a good source of vitamins A and B.

Claims of Manufacturer—Valuable for vitamins A, B and C.

GUNZENHAUSER'S HOLSUM BREAD GUNZENHAUSER'S TIP TOP BREAD

Manufacturer—Gunzenhauser Bakery, Inc., Lancaster, Pa

Description—White bread made by the sponge dough method (method described in THE JOURNAL, March 5, 1932, p 817), prepared from white flour, water, condensed skim milk, shortening salt, sucrose, yeast, powdered skim milk, malt extract, and a yeast food containing calcium sulphate, ammonium chloride, and potassium bromate.

**CERTIFOODS CERTIFIED NURSERY FOODS—
TOMATOES (SIEVED)****VITAMIN CONTENT GUARANTEED, NO ADDED
SEASONING OR SUGAR***Distributor*—Certifoods, Inc., New York a subsidiary of the Maltine Company, New York*Packer*—Curtice Brothers Co., Rochester, N. Y.*Description*—Sieved tomatoes prepared by methods efficient for retention in high degree of the natural mineral and vitamin values, no added seasoning or sugar*Manufacture*—Fresh tomatoes are sorted washed rinsed under high pressure water sprays, scalded, hand peeled and cored, heated to 71 C, sieved in an atmosphere of nitrogen gas, canned, processed and packed as described for Certifoods Certified Nursery Foods—Green Beans (THE JOURNAL, Oct 3, 1931, p 1003) The processing is for twenty minutes at 100 C

ALLERGY IN ANIMALS

There are few phenomena in biology that are as spectacular as the manifestations of hypersensitivity to foreign proteins. It is a startling fact, as H. G. Wells¹ has written in his *Chemical Aspects of Immunity*, that a guinea-pig, which can tolerate many cubic centimeters of such a protein mixture as horse serum in a single dose, will be almost immediately killed by as little as 0.01 cc of the same serum, provided a similar or even much smaller amount has been injected into it ten days or more previously. The character of the death with violent convulsions, perhaps within a minute of the time the injection is made, makes this observation all the more dramatic. The manifestations of allergy are becoming more and more familiar to physicians. They are forced to take cognizance of variations in the reaction of living tissues to foreign chemical agents whether antigenic or nonantigenic in character, or whether the change is toward hypersensitivity or reduced sensitivity. The discovery of the substance responsible for the sensitization or the intoxication of a susceptible patient often taxes the ingenuity of the medical observer to the utmost. One of the most disconcerting discoveries is the circumstance that milk, "nature's most nearly perfect food," may exhibit marked allergic potencies.

The occasional maladaptation of cow's milk to use in the human dietary, especially in infancy, exemplifies how chemically unique the adjustment of exogenous food to the requirements of the body cells may at times become. How a wholesome food may behave like a veritable poison has recently been illustrated in the usual surprising manner by a young walrus, one of the few in captivity, in the pools of the Zoological Society of San Diego, Calif. The animal, a female, was captured at an early age on the ice floes of Bering Sea -

and was fed with meticulous care on evaporated cow's milk, according to the best practices in human infant feeding. Presently a considerable variety of pathologic features manifested themselves. They included skin disorders (reminiscent of the eczematous manifestations of allergy in childhood), disturbances of the mucous membranes, and alimentary dysfunction. Vaso motor rhinitis and gastro-intestinal disorders, as well as cutaneous symptoms, are, of course, familiar evidences of atopy in which milk is involved. In the case of the baby walrus, despite the failure of all attempts to change the physical environment and care of the animal, immediate relief was experienced when milk was completely eliminated from the diet. Such dramatic results should fortify the efforts to relieve some of the most tantalizing manifestations of discomfort in man.

As Wells has pointed out, animals may become refractory to anaphylactic reactions in several ways, namely, desensitization, through exhaustion of the fixed intracellular antibodies by their union with the antigen, antianaphylaxis, when there are sufficient free antibodies in the circulating blood to unite with all the antigen so that it cannot reach the sensitized tissues in which the reaction takes place, antisensitization against passive anaphylaxis, when the blood contains antibodies against the serum that contains the anaphylactic sensitizer since the sensitizing antibodies cannot then reach the tissue cells, and tissue inactivation, when through exhaustion drug action or other injury the sensitized cells cannot respond to the antigen-antibody reaction. In the study of such phenomena lies the possibility of a great therapeutic advance in human medicine.

A PROPOSED NEW INDEX OF NUTRITIONAL STATUS

The subject of malnutrition in children has been discussed in *THE JOURNAL* several times within recent months.¹ In view of the activity in identifying malnourished children stimulated by the Child Health Recovery Conference any new method offered for the ready screening of large groups to identify those who may need more thorough examination is of interest. The American Child Health Association offers what it terms the ACH index of nutritional status. The initials do not refer alone to the sponsoring organization, as might at first be supposed, but to the measurements on which the index has been based - namely, the measurements of the arm (A), the chest (C) and the hips (H). In a pamphlet issued by the association² the index is explained and indications for its use are outlined. It is developed from material previously pub-

lished in the child health monograph series dealing with measures of growth and nutrition³

There has long been a need for a practical measure having the advantages of convenience inherent in the height-weight-age standard but without the disadvantages of that much abused criterion. The starting point for this new index is medical judgment, together with a complete set of measurements, including shoulder breadth, hip width, chest width and depth, height, weight, arm and calf girth, size of the deltoid, and thickness of the subcutaneous tissue over different areas of the arms and legs. Seven measures were then selected as giving the most satisfactory picture, to which additional data did not add anything of appreciable value. These measurements, plus medical judgment, were applied to more than ten thousand children, of varying social and economic status, in seventy-five cities. These measures were hip width, chest depth, chest width, height, weight, arm girth, and subcutaneous tissue over the upper arm. These offered no practical substitute for the simple procedure of weighing the child and measuring his height. They were accordingly narrowed down to three—arm girth, chest depth and hip width. The arm girth is measured with a special steel tape with spring handle, and the hip width and chest depth with wooden calipers devised for that purpose⁴. The technique of measuring is simple and is fully described in the pamphlet. To select cases by this index, the sum of the two chest-depth readings (inspiration plus expiration) are subtracted from the sum of the two arm girth readings (arm flexed plus arm relaxed). The difference is compared, in an accompanying table which is part of the score card, with the minimum difference allowed between the arm and chest measurements in a child with the hip width of the one being examined. The values in the table are based on the ten thousand sets of measurements from which the index is derived. For example, if a boy has a hip width of from 26.5 to 26.9 cm, his minimum allowable difference would be 6.3 cm. If the difference between the sum of his arm measurements and the sum of the chest measurements is less than 6.3, he is selected as one requiring further examination, if it is more, he is not.

This index can be applied in three ways, which are described. The third way, in which the index is used alone, seems to offer the most practical possibilities. It selects about one tenth of a given group and refers them directly to the physician for his further consideration. It is admitted that some cases of serious defect are missed in this way, but the ones most in need of attention are selected. Teachers must in any event be depended on to give their cooperation in any program of discovery involving large groups of children. It is admitted that further study is needed, especially appli-

cation of the ACH index to age groups below 7 and above 12, for whom data are lacking. If larger experience supports the tentative conclusions indicated by this careful study, which has extended over a period of years, great significance will attach to this index. The inexpensiveness and ready portability of the measuring tools, as compared with scale equipment, plus the convenience of the index, should give a great impetus to an overhauling of the antiquated methods still in vogue in many programs for school physical examinations. Economy and increased effectiveness of the school health examination, now loaded with unproductive routine procedures of doubtful validity, await only the development of a ready screening device. The index here advanced should be studied with great care and tested on a large scale to ascertain whether or not this is the answer to the need that has existed for many years.

SPECIAL EXHIBITS FOR THE CLEVELAND SESSION

As the Board of Trustees and the Committee on Scientific Exhibit continue to develop plans for the Cleveland session of the American Medical Association, June 11 to 15, it becomes apparent that even the extraordinary peaks of previous assemblies are to be surpassed. Among the special demonstrations to be made will be not only the fresh pathologic material collected daily from Cleveland hospitals but also three special showings of current interest. These include a complete laboratory exposition of the pathology and methods of diagnosis of amebiasis, material on epidemic encephalitis especially arranged under the direction of those who made studies in connection with the serious outbreak in St. Louis, and an exceedingly practical exhibit of the newer methods in the treatment of burns. Incidentally, these exhibits are correlated with papers and symposiums in the sections, attention has already been called to the general scientific meeting to be held Tuesday afternoon, June 12, in which leading authorities on amebiasis from various portions of the United States will present the most recent and authentic considerations of this subject.

During the Cleveland session two additional unusual features will be meetings of the Section on Miscellaneous Topics devoted respectively to forensic medicine and to nutrition. Here again the annual session of the American Medical Association leads the way in offering to those who attend complete symposiums on topics in the forefront of medical interest. Moreover, the reading of the papers in the symposiums is to be supplemented by extensive displays on these subjects in the Scientific Exhibit. Authorities from some of the leading criminal investigative offices in the United States will combine to present current aspects of the scientific and medical investigation of crime. In the exhibit on nutrition, the more recent applications of diet to the

⁴ Obtainable from the American Child Health Association, 450 Seventh Avenue, New York. Tape \$1.65, calipers \$2.10.

control of disease and to purposes of growth will be shown

As is customary at the annual session, the various sections will also arrange practical showings closely related to the material of their programs. Especially significant as defining a trend in medical thought is the exhibit of the Section on Obstetrics, Gynecology and Abdominal Surgery, which will be devoted to the technic of delivery as carried out in the home. Certainly this is an indication of the willingness of the medical profession to do everything it can toward lowering the costs of medical care without hazarding any depreciation in the quality of care. The Section on Ophthalmology will display the methods of first aid in injuries of the eye, the Section on Dermatology and Syphilology will have an exhibit in allergy, and several other sections are planning exhibits in their special fields.

For many years now the annual session of the American Medical Association has been recognized as the most complete in scope and most largely attended of any medical meetings held anywhere in the world. The Board of Trustees proposes not only to maintain these superlative attributes but also to insure so much in the way of practical graduate teaching in the field of medicine that every general practitioner within reasonable distance of the annual session will feel it his duty to qualify for Fellowship in the Association and attend these meetings regularly.

Current Comment

THE DOCTOR AND THE COMMUNITY

Under the heading Medical Economics, immediately following these editorials, appears a report of a meeting held in Philadelphia recently to consider the relationship of the physician to the community. The program aroused interest, first, because it was a joint meeting arranged by the American Academy of Political and Social Science and the College of Physicians of Philadelphia, and, secondly, because of the nature of the debate that developed. Although the program was planned originally to present the aspects of this topic from various points of view, many members of the medical profession asserted that its chief purpose was to overwhelm the medical profession by pressure from without, leading toward the socialization of medical practice. In order to make clear the nature of the debate that developed, it should be said that copies of the addresses were prepared beforehand, and that the editor of *THE JOURNAL* rewrote his address during the meeting in order to answer some of the critics of the profession who had appeared on the program before him. Thereafter, Mr. Foster, the final speaker, also changed his address to answer some of the statements made by the editor, but copies of his final address were not made available. The program established definitely the fact that Mr. Michael Davis, representing the Rosenwald Fund, is himself opposed to the entire leadership in American medicine today, and that a large

part of his efforts and travels throughout the United States are devoted to attacking that leadership and to undermining organized medicine as it endeavors to function in behalf of the medical profession. It is apparent that at least in some places this undermining has been accomplished with a fair degree of success, either through misunderstanding or with willing cooperation by local authorities in the medical field. Mr. Davis announced, as will be seen in the quotation from his article, that it was the purpose of the Twentieth Century Fund, the Milbank Fund and the Rosenwald Fund to carry on such efforts. It is well that the medical profession be advised of this intention.

THE TUGWELL-COPELAND PURE FOOD, DRUGS AND COSMETICS BILL

This week hearings are to be held in Washington on the second revision of the original Tugwell bill for strengthening and extending the pure food and drugs legislation of this country. *THE JOURNAL* has previously stated its complete support of the principles of this legislation, and the Board of Trustees has officially endorsed that point of view. The legislation has been attacked by the proprietary medical interests and by publishing interests. In fear of the effects of such legislation on advertising, the attack not only has been directed toward senators and congressmen but has been carried on in other ways to influence the public as well. Moreover, several other bills have been introduced by various interests in an endeavor to divert congressional attention from the new Copeland bill, which is said to represent the administration's desire. It is conceivable that, after the hearings which are to be held this week, further modifications will be made in the final revision of the Copeland bill, which is known as Senate Bill No. 2800. There are indeed some aspects of this bill which could not be supported by the medical profession and these have been called to the attention of Senator Copeland. Physicians should not be misled however by the legislative manipulation, which is an endeavor to secure a bill that will pass and yet give to the public the protection that it so much needs. When the original food and drugs legislation was introduced and became effective, advertising had not grown to its present proportions as a leading industry in this country. The growth and expansion of advertising have made it possible for manufacturers to sell goods with false, preposterous and misleading claims, simply because it is the advertising that sells the goods rather than the label on the bottle or on the package. The new legislation is designed primarily to give the public additional protection that it requires against such advertising. Moreover, it includes with foods and drugs the cosmetic industry, which has grown to alarming proportions in the last quarter century. The medical profession should support this legislation with all the strength that it possesses through its advisory capacity to the public on matters of health, and through its direct contacts with legislators. Telegrams to senators and congressmen, indicating the wish of the people for the successful passage of Senate Bill No. 2800, will give the aid that is required toward a worthy cause.

Medical Economics

THE PHYSICIAN AND THE COMMUNITY

The American Academy of Political and Social Science combining with the College of Physicians of Philadelphia held a meeting in that city, February 7, with the apparent purpose of presenting from diverse points of view the problems that arise in the relationship of physicians to the public. The inspiration for this assemblage, according to Mr. Michael Davis of the Rosenwald Fund, came to him approximately a year ago but apparently it required the passage of twelve months for its full blossoming. The mere announcement of the program served to arouse resentment members of the medical profession in Philadelphia asserted that the choice of the essayists had been made deliberately with a view to overwhelming the medical profession. Moreover, members of the Committee on Medical Economics of the Philadelphia County Medical Society charged that the choice of subjects was an attempt to stack the program against the medical profession by emphasizing the socialization of medical practice. Incidentally, no Philadelphia physician had been asked to contribute to the program.

The Sociologist Looks At Medicine

The proceedings opened with an essay by Prof. James S. Bossard, professor of sociology in the University of Pennsylvania. He pointed out that the public attitude toward medicine has changed and he asserted that the large amount of free medical care given to children in the schools, to the soldiers in the World War and to workers in industrial plants, and the increasing participation of the government in medical practice had caused the public to look on medical service as they do on education and police protection.

"Over against this newer public demand for a socialized health service that is adequate, effective, easily available and cheap, if not gratuitous," he said, "stands a very old profession, dominated by individualistic conceptions, formulated through a very long and honored past, composed of men who have undergone a long period of training, who have invested a good deal of money and time and effort in their professional preparation, and who are confronted with the necessity of earning a living in accordance with the investment which they have made in that preparation."

Professor Bossard then presented several maps of Philadelphia on which he had indicated the locations of physicians' offices and of hospitals and the centers of population in Philadelphia. From this he derived the conclusions that poor people do not have medical attention easily available, that specialists are even harder to find than good general practitioners, and that hospitals have been forced by shifting of the population to embark on hospital insurance schemes. He ended with the charge that the leaders of the medical profession, being well entrenched and with no difficulties of earning a livelihood, are reluctant to face changes and that such entrenched stubbornness will lead to violent reaction. Indeed, he suggested the possibility that a refusal to socialize medical service will ride the medical profession directly into state medicine.

Abuses of Medical Charity

The second paper was by Dr. Nathan B. Van Etten, one of the signers of the minority report of the Committee on the Costs of Medical Care and vice speaker of the House of Delegates of the American Medical Association. Dr. Van Etten reported the results of a survey of the abuses of medical charity and of the free services of physicians which had been made in the Bronx in New York City, and he established quite certainly the facts that considerable numbers of people well able to pay are taking advantage of the laissez faire attitude of the medical profession in this regard.

Medical Practice and Public Needs

Next Dr. Edgar Sydenstricker, director of research of the Milbank Memorial Fund, attacked the right of medicine to control itself asserting that the medical profession had considered itself sacrosanct and that all the discussions of the subject were inhibited by medical tabus. He particularly deprecated the editorial in which *THE JOURNAL* first discussed the reports of the Committee on the Costs of Medical Care. In general he was opposed to our whole economic system but particularly as it concerned medicine. Thus he said, "Any program of action to be given serious consideration at present must assume the continuance of the economic system under which we

now live—a system that is characterized by a grossly unequal distribution of wealth and of ability to pay for the essentials or the luxuries of life."

In outlining the approach to the problem, he suggested first the possibility of gradual evolution, which he believes is tending toward group payment and group practice, and toward new emphasis on the general practitioner. The second possibility he considered was mass production by private interests and distribution by prices regulated by the public. The third possibility was government control, and the fourth, compulsory insurance on either a state-wide or nation-wide basis. For various reasons he rejected all of these possibilities and suggested instead a combination of various methods. He felt that Americans could never learn to budget their medical care because the costs were unpredictable. He felt that some insurance system should be developed going beyond the systems already established in Great Britain and Europe and providing every type of medical service to every member of the family of people having incomes below an amount sufficient to purchase medical service in any contingency.

Changing Position of Medicine in the Social Order

The afternoon session opened with a scholarly address by Professor Sigerist of the Johns Hopkins University School of Medicine, which comprised a history of the changing position of medicine in the social scheme. His conclusion was that medicine, being a part of the social order, invariably adapts itself to the needs and arrangements of its time.

Canadian and British Experiences

Dr. Grant Fleming, professor of public health and preventive medicine in McGill University, said that the Canadian medical profession became restless under the burden of the care of the indigent and that the indigent were dissatisfied with the type of medical care they were receiving. The Canadian Medical Association urged that medical care be included with food, shelter and clothing among items of relief. The government refused to do this, asserting that this burden should be laid on the provinces. "The important point in all this," Dr. Fleming said, "is that governments, while recognizing in theory that medical care is one of the essentials of life, leave the cost of the burden to be borne by the medical profession alone instead of distributing it over the whole population."

"The acute situation arising out of the depression," he asserted, "has brought about a fairly general acceptance of the idea that there must be some change in the provision of medical services." He pointed out that certain services are already provided without cost to the public, including the care of the mentally disabled, workmen's compensation and public health services. There is also insurance on an individual basis and in lodges. Moreover in some of the provinces hospital insurance has been established. Some of the provinces have established full time municipal physicians.

In British Columbia the medical association has advocated a system of compulsory, contributory state health insurance providing a complete medical benefit with freedom of choice of physician and payment on a fee-for-service-rendered basis.

The Canadian Medical Association in November, 1932 authorized its committee on economics to prepare a plan or plans for health insurance and to pass these plans to the various provincial associations for their consideration, criticism and suggestions.

Dr. Fleming then traced the progress of the British Medical Association in relation to health insurance. He said that the medical profession of Great Britain has concluded that with all its faults health insurance is the best plan available to provide an adequate medical service for the nation. He said further that the vast majority of the medical profession of Canada believe that a change is coming, that many want a change and that the public is going to insist on having medical care arranged for on a basis whereby they can pay for it without being unduly burdened.

The Renaissance of the General Practitioner

Dr. Roger I. Lee of Boston made an impassioned defense of the general practitioner and cited many of the conclusions of the Commission on Medical Education in support of his point of view. Dr. Lee said that the temper of the public and even the temper of the medical profession is toward further experimentation in modification of the methods of practice. He felt that the patient must always be considered as a unit and not as an aggregation of isolated segments—that there must be some integrating force such as the general practitioner, for the handling of the

patient. He emphasized the relation of the mind to disease and therefore the necessity for intimate personal relationship between the doctor and the patient. He concluded with a statement as to the nature of the general practitioner of the future.

Change Comes to the Doctor

The original title assigned to Mr. Michael M. Davis of the Julius Rosenwald Fund was "A Layman Looks at Doctors." As he thought himself something more than a layman, the title was modified to the one which heads this section.

Almost from first to last, Mr. Davis's address was an attack on leadership in the American Medical Association, including its House of Delegates, its Trustees, its General Manager, its Editor, its Bureau of Economics and its publications.

He began with his resentment at the editorial in *THE JOURNAL* which dealt with the report of the Committee on the Costs of Medical Care. He then asserted that physicians throughout the nation are reorganizing to meet the recommendations of the Majority Report, pointing out that California is leading in endorsing sickness insurance and that a commission in that state is investigating the subject in order to report to the legislature in 1935.

He emphasized that Seattle, Tacoma, Yakima and Portland have county medical societies which have organized service bureaus to provide the public of those cities with medical service on the insurance principle. He mentioned county medical societies in the Midwest and in the East which have developed similar plans and asserted that the medical society of New Jersey has directed the reorganization of health service committees in every county society.

Mr. Davis pointed out that during 1933 he had met with representatives of medical societies in four cities to discuss sickness insurance plans which committees had drawn up. He applauded particularly the state of Michigan, which has authorized its committee to prepare practical plans for establishing demonstrations of sickness insurance and which has sent representatives to England in cooperation with the American College of Dentists to secure a first-hand report on British sickness insurance.

Moreover, he pointed out that the American College of Surgeons has been working on an extensive plan of medical service in industry.

Then he attacked the national organization in medicine for blocking such plans and for fomenting opposition to them. He asserted that the Milwaukee plan was blocked by an influence coming from Chicago, that a similar plan in Nashville which he had helped to originate was blocked by one of the officials of the American Medical Association. He asserted that an effort had been made to dissuade the American Hospital Association from endorsing group hospitalization and that the editorials in *THE JOURNAL* have never encouraged the experiments that he advises.

He assailed *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION* for failing to endorse the British system and the London correspondent of *THE JOURNAL* for misrepresenting that system. He accused the Secretary of the American Medical Association of misrepresenting an address by Sir Henry Brackenbury in abstracting that address for the *Bulletin of the American Medical Association*.

Then he commended the American Hospital Association for its approval of group hospitalization and described plans developed by Cleveland, Newark, N. J., and Akron, Ohio for such hospital insurance.

Next he endorsed the plan of medical care under emergency relief developed by the Roosevelt administration, asserting, however, that the system is bad because it does not provide for the hospitals and the clinics. He emphasized the manner in which the clinics have expanded during the depression and feels that this is a demonstration of the ultimate change which is coming in medicine. He asserted that only from 2 to 5 per cent of those who use the clinics are actually able to pay.

Then Mr. Davis endorsed group dental practice, and finally he pointed out that the Milbank Memorial Fund, the Twentieth Century Fund and the Julius Rosenwald Fund are exceedingly active in organizing sickness insurance plans and aiding new projects for group hospitalization.

He expressed his resentment at the editor of *THE JOURNAL* because the latter has opposed this type of lay interference in medical practice.

"As one sums up the developments of the last few years," he said, "one is led to contrast the reactionary expressions of some professional bodies with what thousands of physicians and

hundreds of medical organizations throughout the country are now doing. Actions are more conclusive than words, and it is a most significant and encouraging fact that the organized actions of physicians during the past few years through medical societies, hospital staffs and clinic groups represent a larger measure of professional initiative and participation in sickness insurance and other organized projects than appeared in any European country during the period when these undertakings were in their formative stage. The movements abroad were almost exclusively initiated from industrial sources."

He then attacked a national medical official for expressing an "ostrich philosophy" in saying that "this agitation about the costs of medical care will all die down if we just keep things quiet for a while," and he suggested that the public could take care of physicians and medical societies who express these principles without much hesitation.

Americans do not want," he said, "and nobody ought to have, a cheap or impersonal doctor. Nobody questions that the physician is the authority about caring for the sick, but, as to the system under which medical care is to be organized and paid for the people who are the ultimate consumers and who meet the bills of the service must have more than a little to say. The American people are likely to be impatient of those who do nothing to aid experimentation and have nothing themselves to propose except the philosophy of keeping things as they are."

The Health Officer and the Community

The evening session opened with an address by Dr. Thomas P. Pirran, health commissioner of New York, who outlined the manner in which the state now enters into medical care and who urged gradual evolution, experimenting with various schemes of practice, as a hope for the future.

The Doctor and the State

Dr. Morris Fishbein, editor of *THE JOURNAL*, said "The time has long since passed when the family doctor in his relationships to his patients represented complete medical responsibility and care." He pointed out that the medical profession has long since recognized the right of the state to concern itself with preventive medicine as it affects community in the mass.

However, the medical profession has during the past quarter century, been confronted with many facts indicating the desire of the state to enter more fully into the problems of medical care. It has seen the extension of free clinics. It has participated in a multitude of surveys and demonstrations. It has witnessed innumerable attempts by the state to contract for medical care under a variety of conditions. It has observed the establishment in most of the large universities of health services which undertake to provide complete medical care for students, faculty and employees.

It has noticed the attempts of health officers in some communities to broaden unduly the scope of their work. In most plans medicine has given largely of its services and made for their success.

Without the cooperation of the medical profession, no system of medical practice can succeed. One listens with amusement, if not with amazement, therefore, to the threats of many of the leaders of the organizations that have been encouraging wide spread propaganda for nationalization of property and socialization of personal service when they say to the medical profession that unless it socializes itself socialization will be forced upon it. No well organized body can be forced into any position. The medical profession as an intimate part of our nation, will no doubt, indeed, already has participated in the general trend of our government. There has been in our government a trend toward socialization for some twenty years. It is interesting to realize, as was pointed out by the president of the Indiana State Medical Association in a recent address, that all but two of the planks in the socialistic platform of 1912 have today become part of the law of our land. Nevertheless, those who know and understand the nature of medical care, including particularly the diagnosis and treatment of disease in the individual, are inclined to believe that the last stand of the citizen in maintaining his status as an individual human being is going to be in times of disease. A man at work in a gang along the side of the road, a soldier who is a fragment of humanity in a regiment of cannon fodder, a robot in one of our great industrial plants who spends minute after minute, day after day, performing the same mechanical functions, has but little opportunity to feel that he is an individual human being. But when a splinter of steel flies into his eye when his shoulder begins to ache with the stress of the pick and shovel or when he inadvertently takes into his system

a large dose of *Endamoeba histolytica* with drinking water which he has been assured by the state is quite free from contamination, he begins to realize that there are parts of his body that have no realization of the state's desire to care for him. Those parts make their presence known in a most disagreeable manner. At such times he seems to prefer a physician who will look at his eye not as an eye belonging to the state but as an eye belonging to John Smith. He prefers a physician who will treat his amebic dysentery without any relationship to the state's responsibility for having permitted the conditions that caused that dysentery to develop. He finds himself in his relationship to the state exactly as he finds himself in his relationship to an employer who wants from his labor all the work that he can get but who wants to pay to his labor the least that can be paid. Those who have watched the tender care of the state for the public in times of stress realize that the sympathy, the understanding and the humanity of state employees toward the unfortunate is not always manifested with what might be called humanism. Those who have read in "Little Man, What Now?" the experience of the German laborer who was trying to get from his government something in the way of benefits under the insurance act in Germany will find a startling example of the way in which bureaucratic employees under most circumstances concern themselves with the problem of the individual sick man.

"There is hardly one of the socialized medical services and the state medical services that have been developed in various parts of the world that has not constantly been subjected to criticism of political manipulation. The answer of those who would socialize medicine to the charge that under a system conducted by physicians politics would not enter into the picture is in itself too naive to merit consideration.

"As long as men are human beings they will continue to react personally on each other. As long as nations are subject to political manipulation, contracts between a nation and the individual in the nation are merely matters of form. Consider what happened in Germany to its social insurance scheme when the Hitler regime took over the reins. What then of the contracts held by physicians with various sickness organizations? What then of the high standard of medical practice set up in Germany under a different reign? What of the resolution which was promulgated by the new government licensing 5,000 naturopathists and telling the medical profession to turn its face to the naturopathic system of practice. Such are the possibilities in medical care when a nonmedical government is in the saddle.

"What of Russia with its sovietized system of red medicine so sympathetically and joyously considered in the recent writing of Messrs. Newsholme and Kingsbury? Their 9,000 mile jaunt in four weeks obviously gave them opportunity to see all the best that red medicine had to offer, but the review of their observations in the *New York Times* brings to light the remarkable vagaries of their health inspection tour and leads an enlightened reviewer to conclude that it resembles nothing like a scientific investigation of the facts.

If there is any one fact apparent in relationship to all the systems of state and socialized medicine that have been developed throughout the world it is that not one of them has been established as a success. There is not one of even the most prejudiced investigators of such systems who is willing to say that the United States today should establish a similar system for the people of this country. But with the folk that has inevitably characterized the projectors of fantastic schemes for social reorganization, perhaps with an inordinate pride in American democracy, those who urge the socialization of medicine insist that where others have failed with such systems Americans will be sure to succeed.

By 1932 the nation was in the midst of an economic depression from which there is doubt as yet that it has wholly emerged. Perhaps the economists will function satisfactorily as physicians to the nation in its time of depression, but it is doubted that they have the knowledge to cure the social evils which are basic in the nature of man. It is doubted that they know enough about the mind and body of a man diseased to organize a system for his cure. Indeed even the methods of cure for the economic difficulties of the nation are in that stage of science in which medicine was at the time of Hippocrates. They offer remedies for the nation's economic troubles as the physician of today endeavors to treat arthritis knowing of no specific cause of arthritis he recommends salicylates and cinchophen he uses hydrotherapy, diathermy and rest in bed and massage and then is still ready to send the patient to a hot climate and to recommend consultation with three more specialists.

I have said that the question of the attitudes of the speakers is fundamental to a consideration of the subject. Any one who

had studied the bibliographies of the members of the Committee on the Costs of Medical Care could have told long before its report was issued what the nature of the report would be. Since the announcement of the meetings held here today, physicians have written in considerable numbers pointing out that the program seemed to be stacked against the medical profession, for the medical profession as a whole is quite familiar with the points of view not only of its own representatives on this program but also of Sydenstricker, Michael Davis and Parran, and with the views of William T. Foster, who follows me. It is not surprising to hear Sydenstricker assert that the profession is bound by tabus and traditions which must be overthrown, neither is it remarkable to hear him insinuate that our entire economic, social and political system needs reorganizing. It is annoying, however, to have him center his attention on medicine and want to begin all the reorganization with the medical profession. Yet as an employee of the Milbank Foundation, what other course is open to him? That foundation is pledged to a program for socialization of medical care and its executive secretary, Mr. Kingsbury, has become enamored of what was shown to him in a personally conducted tour of Russia.

'No better proof of the necessity for medical advice in a study of medical matters could be offered than Professor Bossard's analysis of the distribution of physicians and hospitals in Philadelphia, of his attempt to trace an analogy between university health services and military medical services offered to special classes of the population under peculiar conditions with the medical care that must be given to people generally, living in their own homes and subject to all of the vicissitudes of existence, such as lack of fuel, bad housing, improper nutrition and want of many of the other necessities of a bare existence. He points out that the poor suffer much more with illness than do the rich, but he does not attempt to cure them of the cause of their illnesses, which lies largely in their poverty. Quite unscientifically and wholly unmedically he would not attack the cause of their illnesses but worries about diagnosis and treatment after the illnesses develop. His maps of the distribution of physicians in Philadelphia prove just one thing—that a patient will travel many miles and pass by the offices of innumerable competent doctors from a legal and scientific and educational point of view to get the doctor that he wants to take care of him. And Professor Bossard ends his discussion with the same old threat. If the doctors do not give us what we want, there may be violence. Well, the doctors in Germany and France and in England have been giving the people what the politicians and the economists said the people wanted and there is violence. And a hundred competent observers, including many in high places, do not find the vast majority of the people of the United States dissatisfied with the type of medical care available to most of them today.

'It is asserted by both Messrs. Sydenstricker and Davis that the organized medical profession does not today represent the majority of physicians. If it does not, then the Congress and Senate and the President of the United States do not represent the people, because the American Medical Association has been since 1901 organized and conducted on a strictly democratic representative basis. He accuses the secretary of the Association and myself as editor of having failed to represent conditions here and abroad adequately to the profession and then he fills his manuscript with quotations from *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION* to prove the value of the foreign systems of practice that he supports. Mr. Davis indicts the medical profession because of its opposition to certain plans of hospital insurance. He fails to point out that in the period of prosperity, when money was spent in madness, hospitals over-expanded, attempted to ape the wealthiest hotels in their constructions, provided for nurses in their competition to get free nursing service with dance halls, swimming pools, libraries and great reception halls, and then, when caught by the depression, in many instances tried to save themselves by bankruptcy through the development of schemes that would disrupt, disorganize and exploit the medical profession. He forgets that the quality of service rendered by any hospital can be measured only by the quality of the physicians who compose its staff. And finally he fails to state how many of the experimental schemes to which he points with pride were initiated by personal visitations from members of the Milbank and Rosenwald funds, subsidized by money coming from these funds and promoted with propaganda paid for by these funds. So far as any of the experiments have succeeded, and no one can say now whether or not any of them will succeed they have been made possible by the tolerance and cooperation of the organized medical profession. The American Medical Association has never opposed honest scientific experimentation. But it has asked that the game be played according

to the rules laid down by a thousand years of tradition and experiment. The rules were made to safeguard the interests of the sick individual, not, like the rules of so many of our philanthropies, to make a vast number of people dissatisfied with their hours of work and the wages they receive complacent because somebody else pays for the cost of their illnesses. The famous sociologist Ross, talking of philanthropy with strings, points out that medical care on a philanthropic basis has come to be the philanthropist's panacea for social unrest.

"In the paper of Mr. Foster, who is to follow me, you will hear a remarkable solution to the problem of medical care. It is briefly the conclusions of the majority report of the Committee on the Costs of Medical Care. That report, which has, except for gatherings of little groups of serious thinkers such as this one, lapsed into innocuous desuetude, that report which is kept alive only by the propaganda which is financially sustained by the Milbank and Rosenwald funds, would remove from physicians the right to say how medicine shall be practiced and put it in the hands of nonmedical directors. It is useless to attempt to distinguish between the content of medical practice and the method of administration. The whole question of mutual responsibility between patient and physician is basic. Shall the doctor be responsible to the patient whom he serves, protecting the interests of the patient and considering those interests first or shall he be responsible to the industry which employs the patient, the insurance company which insures him, the government which dictates to him, or the hospital to which he consigns his body in times of sickness? Shall the doctor or the insurance adjuster say how long the patient is to lie in bed after an operation for appendicitis? Shall the doctor or the employer say when the sick man is able to come back to work? I must insist that these are questions which only a physician with the patient as his first interest is able to answer satisfactorily for that patient.

"The medical profession has witnessed some interesting spectacles of late. It has seen a Hugh Cabot who argued for social insurance and state medicine come back from abroad and announce that the standard of medical care in the United States today is better than he found it in five foreign countries. It has seen England disturbed by fear that its system of compulsory health insurance would bankrupt the nation as it has already bankrupted the voluntary hospitals, and it has seen politicians offering as a cure for the situation more social insurance. *Similia similibus curantur*.

"The majority of American physicians have not been greatly concerned about the entrance of the state into medical practice, and Walter Lippmann says that the people generally are even less concerned. In most communities there have been departments of public health which are able to accomplish results in preventive medicine by cooperation with the medical profession. Some of these departments have entered much more fully into medical practice than others. Gradually health departments in some places encroached on the province of the medical profession. When money was freely available, some even attempted to conduct periodic physical examinations. Then came the depression, and with the depression a tremendous lowering of budgets of health departments. When these budgets were lowered, health departments discontinued most of their services to the individual and concerned themselves more and more with those functions involving the prevention of disease by the control of the water supply and of the food supply, the disposal of sewage and the control of epidemics. These may be considered well established functions of health departments.

"Beyond these phases of government participation in medical care there was also the Veterans' Bureau. It would be useless to attempt to repeat here the complete story of the manner in which the veterans through political activity obtained for themselves not only cash compensation but also the right to complete medical care without cost in government hospitals by full time government physicians. However, again, when the depression arrived the government was able to see the folly of giving complete medical and surgical care to men who had been veterans and who were well able to pay for such care when the illness or disability bore no relationship whatever to the government service. It is needless, incidentally, to remark that once having been at the trough the veterans are moving heaven and earth to squeeze their way in again.

"And now comes the present administration with all of the various methods for overcoming the depression that have already been mentioned. Each of these is associated to some extent with medical practice.

"In all of these efforts of the government the medical profession has participated, realizing the existence of the emergency.

No doubt the entire program has been in itself a sort of insidious propaganda for state medicine among the persons who received the benefit and among a considerable number of almost indigent physicians who have been enabled thereby to benefit somewhat their financial status.

"The medical profession has, moreover, been lending itself in various ways in various parts of this country to innumerable other experiments in medical care. Contract practice, industrial practice, hospital insurance schemes, university practice, lodge practice and group clinics are a few of the many forms of medical care now available in various communities, and these simply could not exist without the services of some of the medical profession.

"There are certain criteria by which scientists measure the results of various experiments. In consideration of many of these sociomedical experiments, the scientific criteria have been waived or overlooked. It would be desirable to know first of all whether morbidity and mortality rates in communities where these experiments exist are lower than those in other communities in which the old form of medical practice prevails. Actually, however, no satisfactory scientific statistical data are available to show that sickness and death, even among the low income classes, are lessened after any of these plans for the distribution of medical costs are put into effect.

"It is realized that advance payment covering the cost of sickness is likely to prolong the illness. It is realized that advance payment is likely to cause the patient to consult the physician much more frequently than he would otherwise. This very psychology in itself tends to invalidate a great deal of the statistical data that are made available.

"In European countries with compulsory health insurance schemes the amount of sickness has not been reduced. Moreover, the death rate, which is much more accurate does not seem to be affected in any measurable manner by the introduction of these schemes or by any other method of paying for medical care. In fact it is safe to say that the mortality and morbidity rates in the United States are as low as or lower than those of most civilized countries.

"In reading a vast amount of literary material on this subject I have been struck repeatedly by the statement appearing in the papers of most of the socially minded writers to the effect that medicine is proceeding in a stage-coach or on a bicycle while the world is traveling on an express train or in an airplane. Medicine has always been rather proud of its conservatism. If it had leaped at once to embrace all of the half-baked schemes that have been offered for changing the nature of practice, if it had hastened in its acceptance of thousands of theories of the causation of disease and of millions of panaceas and cures for various disorders, the effects on humanity would have been disastrous. Nevertheless, medicine points with pride to the fact that it has made more progress within the last fifty years than in all the previous years of its existence. As a result of this progress, increasing years of life have been conferred on most of civilized humanity, and the fear of pain, disease and death has been abolished. No doubt the very abolition of this fear has given the world the opportunity for most of the progress that it has made in other fields.

"Nevertheless, with all the progress that it has made, medicine is not yet ready to say to the world that it has standardized mankind. It still finds individual human beings so definitely individual in times of illness that they are not to be handled in the mass. True, even when they are handled in the mass it is possible to benefit ailing human bodies. But there is a great distinction between the quality of medical care that can be rendered to mankind in the mass and the quality that is given to an individual. As I have said previously, medical care can be judged only on the basis of the quality of the service rendered.

"It is conceivable that out of many of the experiments that have been made and that are being made and out of the scientific advancement of medicine itself there may develop a greater and greater tendency toward discounting individuality in medical care. However, the scientific studies of recent years reveal no such tendency. We have seen instead in this period the growth of such a method as psychoanalysis, which requires the closest possible communion between an individual physician and an individual patient for hundreds of hours in order to get at the basis of a great deal of physical and mental disease. Under no system of state medical care is there provision for adequate psychologic investigation and mental hygiene.

"We have seen in this period a reaction of the body of man to this new speed of civilization. A lowering of life expectancy at birth instead of a continued increase begins to reveal itself.

Perhaps the machine age is bad for the health of man. Is it not conceivable that the great machine age in which we take such pride, that the great production in industry which seems to such men as a Ford and a Filene to represent the apotheosis of the purpose of mankind in this world represent a wrong philosophy of human life? The medical profession feels that the sick man is still an individual, a human being. Until it is convinced by properly controlled scientific data that its point of view is wrong, it is likely to continue to insist on the basic idea of personal relationship between doctor and patient as the necessary foundation for good medical care. It has shown repeatedly its willingness to work with economists, sociologists and statesmen toward schemes for making such individual medical care possible for the vast majority of our people."

The Consumer's Point of View

Mr. William Trufant Foster of Newton, Mass., an economist of note, now at work organizing a consumers' league, said

"At least one hundred thousand persons in the United States sorely need hospital care today but are not getting it. Why not? The answer seems to be that only two thirds of the beds in our private hospitals are in use, and the hospitals do not know what to do with their surplus capacity.

"At least seventy million persons in the United States whose teeth are decaying are not receiving adequate dental care. Why not? That is because this country leads the world in dental science and has tens of thousands of partially unemployed dentists.

"Many millions of men, women and children suffer from other preventable diseases. Why is nothing done about that? The answer is that the science of preventive medicine has made marvelous advances in recent years, and tens of thousands of competent physicians are eager to use their new knowledge and their idle hours to save humanity from needless suffering.

"These are mad riddles of the Mad Hatter. The riddles and the answers provide another chapter for Alice in Wonderland.

"Under the prevailing form of medical service—private individual practice—more than 80,000,000 persons in the United States either do not receive the care which they need and which could readily be provided or are heavily burdened by its costs. At the same time, many of the competent practitioners and agencies are underemployed and poorly paid. A barrier, mainly economic, stands between the doctors, dentists and nurses who are able and eager to serve and the patients who are sorely in need of services.

"Even in places where adequate medical care can be purchased, most of the persons in the lowest income groups do not get it. In spite of the large volume of free work done by hospitals, health departments and individual practitioners, and in spite of the sliding scale of charges, it appears that each year nearly one half the individuals in the lowest income group receive no curative professional medical or dental attention.

"Even more extensive is the failure of the people to benefit by preventive medicine. In any one year, fewer than 7 per cent of the population have a complete or even a partial physical examination.

Another difficulty is that the patient does not know what he wants. How can he know? And even when he does know, he cannot tell where to find it. As a result, medical care is now bought with little knowledge of its price. The patient commits himself to an unknown course, in which one bill may merely breed others. The price does not behave the way prices behave in textbooks on economics.

"Worse still, under the present 'fee-for-service' basis of private practice, the patient may fall into the hands of fee-splitting doctors and thus be misled when he thinks he is getting honest advice. Fee splitting increases the cost of professional care, degrades the profession and, in effect, puts the patient in the hands of the highest bidder."

What every sick person needs, evidently, is a single agency, in one place, freed from every taint of commercialism, which will furnish him all the necessary information.

The crux of the problem evidently is to bring doctors, dollars and diseases into such helpful and continuous contact with each other that the practice of medicine can keep pace with the science of medicine.

This evidently must be done by collective action. Medical services both preventive and therapeutic should be furnished largely by organized groups of physicians, dentists, nurses, pharmacists and other associated personnel. Such groups should be organized—preferably around a hospital—for rendering com-

plete home, office and hospital care. The form of organization should encourage the maintenance of high standards and the development or preservation of a personal relation between patient and physician.

"The costs of medical care should be placed on a group-payment basis, through the use of insurance, through the use of taxation, or through the use of both these methods. This is not meant to preclude the continuation of medical service provided on an individual fee-basis for those who prefer the present method.

"This whole program, however, is bitterly opposed by those unprogressive persons who have acquired control of the American Medical Association. They appear to be a recalcitrant minority of the profession, similar to the obstructive minorities which Mr. Roosevelt has deplored in certain industries. On account of my personal acquaintance with hundreds of physicians, virtually all of whom repudiate the backwardness and the politics and the tactics of the American Medical Association, I cannot bring myself to believe that the Association represents the profession.

"This is not a conflict between patients and doctors. It is a conflict between reactionary doctors and progressive doctors. It is merely one phase of the war, now being waged in every profession, between those who imagine that we can still live in an economic age that is gone, and those who realize that we are living in a new economic age.

"It is only yesterday, in the countless centuries of human history, that we took over the education of youth as a public responsibility. Before that, formal education was enjoyed only by those individuals who wanted it and could afford to pay for it. The private practice of education failed, and it failed through no fault of the private practitioners. Now we all realize that the state, for its own protection, must require every one to go to school, whether he wants to go or not, and whether or not he can pay the bills. This is one of the fields in which individualism, however rugged, is not a sufficient protection of society. We tried it out for centuries. For centuries it failed.

"All this is equally true of medical care. For centuries we have relied mainly on individual initiative. For the most part, each individual has been free to care for his health, if he wanted to, and to neglect his health, if he preferred to do that, or could not pay the bills. The result is the shocking condition of the rank and file of our citizens, as revealed by the physical examination of the drafted men in our army and navy. Rugged individualism has failed. The private practice of medicine has failed, and this through no fault of the private practitioners. At least seven men and women out of every ten, to cite a single example, have failed, even in times of prosperity, to receive adequate dental care. Yet health is not one of those personal matters with which we need not be collectively concerned. The health of the public is just as necessary for the safety of the state as the education of the public. The analogy is sound in every essential. That is the reason, apparently, why the recalcitrant minority of the medical profession vehemently object to any mention of the analogy.

"Society must look forward to providing for health on the same basis as education, or else leave the medical profession in its present unfortunate plight. Even the chairman of the minority committee of the Committee on the Costs of Medical Care admits that 'a tide of public opinion inimical to the profession is rising which has already become a distinct menace.' For the sake of both the profession and the public, the dollars should be provided by collective action, the doctors should be professionally in command, and thus the abundant resources, human and material, which are already at hand should be mobilized for the age-old battle against disease.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION confuses the issue when it says, editorially, 'The right to say how medicine shall be practiced must remain with the medical profession.' Nobody proposes that lay boards shall tell surgeons how to operate for cancer, or physicians what to prescribe for pneumonia. Nobody suggests any interference with the science of medicine. On the contrary, the aim is to free the science of medicine from the present chaos of the economics of medicine. What the public demands is the right to say, not how medicine shall be practiced, but how it shall be purchased and paid for. Who has a better right to decide that than those who do the paying? In any event, is it folly to burden physicians any longer with business affairs which they have notoriously mismanaged, for which they are not trained, in which they are not interested, and which interfere with that single-hearted devotion to patients which is the glory of their profession?"

Association News

ABSTRACT OF MINUTES OF MEETINGS OF BOARD OF TRUSTEES HELD AT HEADQUARTERS, CHICAGO, FEB 15 AND 16, 1934

The Board of Trustees held a two day session in Chicago, Feb 15 and 16, 1934, during which the affairs of the Association received careful deliberation

LAWSUITS

The Board was notified that the suit filed by John R Brinkley has been dismissed and the costs assessed against the plaintiff

OFFER OF A HOME FOR THE CARE OF TUBERCULOUS PHYSICIANS

The Board declined an offer to take over an institution as a place for the care of tuberculous doctors and medical students and possibly tuberculous nurses, it being considered inexpedient for the Association to accept the offer at the present time even if its charter will permit

ELECTIONS

The following appointments were made for the various councils, committees and editorial boards Council on Pharmacy and Chemistry—Drs Stanhope Bayne-Jones, Eugene F Du Bois and C W Edmunds to succeed themselves, and Dr Kenneth D Blackfan to succeed Dr Alfred Hess (deceased) Council on Physical Therapy—Drs Harry E Mock, George M MacKee and Ralph Pemberton to succeed themselves Committee on Foods—Dr E M Bailey to succeed himself, and Dr Joseph Brennemann, Chicago, to succeed Dr Julius H Hess Committee on Scientific Research—Dr Noble Wiley Jones to succeed himself *Archives of Internal Medicine*—Dr Reginald Fitz, *American Journal of Diseases of Children*—Drs W McKim Marriott and John C Gittings, *Archives of Neurology and Psychiatry*—Dr Stanley Cobb, *Archives of Surgery*—Dr Everts A Graham *Archives of Otolaryngology*—Dr John F Barnhill, and *Archives of Ophthalmology*—Dr Francis Heed Adler—all to succeed themselves *Archives of Pathology*—Drs S B Wolbach and O T Schultz to succeed themselves, and Dr Frank R Menne, Portland, Ore, to fill the unexpired term of Dr William Ophuls (deceased) *Archives of Dermatology and Syphilology*—Dr Fred D Weidman, Philadelphia, to succeed Dr Jay Frank Schamberg

REQUEST FOR CERTIFICATE OF MERIT OR PRIZE FOR OUTSTANDING CONTRIBUTION TO SURGERY

The Board declined to comply with a request for a certificate of merit or a prize in surgery, to be known as the American Medical Association prize in surgery, for the individuals or groups of individuals making outstanding exhibits in surgery at the meeting of the National Medical Association, in view of the policy of the Association to offer prizes only to participants in its own exhibits

APPROPRIATIONS

Appropriations were made for the conduct of the work of the various councils, bureaus and committees in the headquarters office as well as for exhibits and for research work

BROADCASTING PRIVILEGES

Due acknowledgment was made by the Board of the broadcasting privileges granted the Association by the National and Columbia broadcasting companies for weekly talks for the enlightenment of the public in matters of health The outlets of these two companies extend from Canada to the Gulf and from the Atlantic to the Pacific Ocean the facilities made available include more than sixty stations and the time allotted is worth many thousands of dollars

MISCELLANEOUS

Many other subjects received careful consideration Some of these have been laid on the table others were referred to various bodies or individuals for further deliberation and report and will come before the Board again in the near future

COUNCIL ON MEDICAL EDUCATION AND HOSPITALS

Abstract of the Minutes of the Council Meeting of February 11

UNIVERSITY OF GEORGIA SCHOOL OF MEDICINE

A resolution was adopted that approval of the University of Georgia School of Medicine be withdrawn at this time with the provision that this decision will not prejudice the transfer of the students enrolled to other class A medical schools at the end of the college session

ENROLMENT OF STUDENTS IN GRADUATE SCHOOLS

A resolution was adopted that graduate schools must determine their own policy with respect to the enrolment of students.

EARNED AND UNEARNED DEGREES

It was resolved that the Council on Medical Education and Hospitals in no case will recognize an unearned degree as a substitute for an earned degree

LISTING OF INTERNSHIPS

It was resolved that the suggestion for listing internships as to duration character of service and ratio of private and house cases be adopted, or some similar scheme, convenient for classification, indicating the type of intern experience offered in the approved hospitals

NECROPSY PERCENTAGES

It was resolved that cases removed from the jurisdiction of a hospital by coroner or medical examiner, and in consequence not available as teaching material for interns, may be deducted from the total hospital deaths in computing necropsy percentages This provision also extends to bodies legally assigned to qualified educational institutions for dissection

ADVISORY BOARD ON MEDICAL SPECIALTIES

Dr Louis B Wilson of the Mayo Clinic explained the newly created Advisory Board on Medical Specialties He asked for the cooperation of the Council on Medical Education and Hospitals as indicated in the proposed constitution Thereafter, the following two resolutions were adopted

That the standards of the existing boards should be analyzed and that the Council on Medical Education and Hospitals should approve as soon as practicable standards for such special boards with a view to submitting them to the House of Delegates of the American Medical Association at the Cleveland meeting

That the secretary be instructed to notify the Advisory Board on Medical Specialties that the Council deems it inadvisable to accept membership in the Advisory Board in conformity with the constitution recently adopted, but that, should the Advisory Board so desire, this Council would arrange to be represented at the meetings of the board but without voting power and without accepting any responsibility for decisions reached by the Advisory Board

MEDICAL BROADCASTS Columbia Broadcasting System

The American Medical Association broadcasts on a Western network of the Columbia Broadcasting System each Thursday afternoon on the Educational Forum from 4 30 to 4 45, Central standard time The next three broadcasts will be as follows

March 8	Keeping Your Health	W W Bauer M D
March 15	The Health of the School Child	W W Bauer M D
March 22	Progress of Surgery	Morris Fishbein M D

National Broadcasting System

The Association broadcasts on a coast-to-coast network each Monday afternoon from 4 to 4 15 Central standard time (5 o'clock, Eastern standard time, 3 o'clock, Mountain standard time, and 2 o'clock, Pacific standard time) The next three broadcasts will be as follows

March 5	Dangerous Drugs	Paul Nicholas Leech Ph D
March 12	Consistent Inconsistencies	R G Leland M D
March 19	Mechanization of Medicine	Morris Fishbein M D

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES NEW HOSPITALS EDUCATION, PUBLIC HEALTH ETC.)

COLORADO

No More Hospitals Needed at Present—A resolution adopted by the committee on medical economics, January 3, urges the Colorado State Medical Society to disapprove the construction of any hospitals or related institutions until it is evident that existing facilities are inadequate. The resolution, based on the fact that the bed occupancy of these institutions in the state has been below their capacity for years, was confirmed by the board of trustees, January 9.

Society News—At a meeting of the Medical Society of the City and County of Denver, January 19, the speakers were Drs Ward Darley, on "Use of Postpituitary Extract for the Acceleration of Drainage from the Urinary Pelvis", Roy P Forbes, "Intestinal Intoxication A Retrospect of the Changing Treatment and Its Relation to Mortality", Constantine F Kemper, "Anterior Pituitary Gland Newer Concepts in Outline," and Casper F Hegner, "The Approach to Upper Lobe Pulmonary Cavities"—Dr Royal C Adkinson, Florence, was the principal speaker before the Fremont County Medical Society at Canon City, January 22, on "Artificial Pneumothorax"—At a meeting of the Larimer County Medical Society in Loveland, January 3, Dr Thomas D Cunningham, Denver, spoke on "Chronic Arthritis"—A pediatric clinic was conducted at Children's Hospital, Denver, January 18, under the auspices of the Colorado State Medical Society.

CONNECTICUT

Dr Edwards Made Acting Health Officer—Dr Herbert R Edwards, director of the bureau of tuberculosis, was appointed acting health officer of the New Haven Health Department, succeeding Dr John L Rice, who resigned to become health commissioner of New York City. Dr Rice was granted a leave of absence for one year.

New Haven's Health—For the fourth consecutive year, no deaths were reported in New Haven in 1933 from typhoid, scarlet fever or measles, and a new low total (four) in deaths from common communicable diseases was attained. No small-pox was reported during the year. There were 241 new cases of tuberculosis reported in 1933, a decrease of ninety-three from 1932.

Pediatric Prize Awarded—The New England Pediatric Society presented the John Lovett Morse Prize to Dr Jacob Greenberg, New Haven, at its annual meeting in Boston, Dec 15 1933, for his paper on "An Attempt to Reproduce Celiac Disease Experimentally in Young Animals by Eliminating the External Pancreatic Secretion from the Intestine." Dr Greenberg, who graduated at Yale University School of Medicine in 1933, is associated with the New Haven Hospital. The prize of \$150 is offered annually by the New England Pediatric Society for the best dissertation on subjects of clinical or scientific interest in pediatrics. Only fourth year medical students of class A medical schools in New England are eligible to compete. Information regarding the prize may be obtained from the society, 319 Longwood Avenue, Boston.

DISTRICT OF COLUMBIA

New Surgical Society—The Washington Academy of Surgery was organized, Dec 8, 1933. Among the requirements for membership are eight years of practice with limitation of work largely to surgery or its allied branches, and certification of ethical standing and ability in the practice of surgery. Regular meetings will be held four times a year on the second Friday in February, April, October and December in the library of the Medical Society of the District of Columbia. Officers of the new organization, to serve two years, are Drs Harry H Kerr, president, Frederick R Sanderson, vice president, and Dr Alex Horwitz, secretary.

GEORGIA

Rat Eradication Campaign—Plans have been launched in Georgia to exterminate rats in an effort to eliminate typhus fever from the state. Financed by the Civil Works Administration the activities will be concentrated in Atlanta, Brunswick and Savannah, newspapers report.

Society News—Dr James N Brawner presented a paper before the Fulton County Medical Society, January 18, on "Cerebral Inhibitory Functions and Their Disorders as Related to Mental Symptoms." Dr Dunbar Roy presented a paper on "Epiphora in Infants and Its Treatment" before the society, February 1.

Personal—Dr William L Gilbert has been named health officer of Fulton County, succeeding the late Dr William N Adkins—Dr William A Palmour, Gainesville, assumed his duties as city commissioner, January 1, for a term of three years—Drs Lovick P Longino and James I Garrard, both of Milledgeville, were recently elected medical director and superintendent, respectively, of the Milledgeville State Hospital—Dr James R Dykes, Cairo, was recently reelected commissioner of health of Grady County—Dr James H Jackson, Barnesville, has been elected health commissioner of Lamar County.

ILLINOIS

No Tuberculosis Deaths in County—Schuyler County reported no deaths from tuberculosis for 1933, according to the state department of health. Low figures for other sections of the state suggest a continued improvement in the death rate for tuberculosis, although other evidence indicates a definite increase in prevalence. The tuberculosis death rate in 1933 was the lowest on record for Illinois.

State Society Urges Enforcement of Medical Practice Act—At a meeting of the council of the Illinois State Medical Society in Springfield in January, a resolution was adopted urging the state department of registration in medicine to enforce the "plain provisions of the Medical Practice Act." It is common knowledge, the resolution points out, that corporations are actively, openly and flagrantly violating the medical practice act, as evidenced by advertisements in the press and over the radio. The practice of medicine as a business by a corporation, even though the employees of the corporation are licensed physicians, and the professional connection or association with or lending one's name to another for illegal practice are direct violations of the medical practice act, it was said.

Chicago

The Mathews Lecture—Dr Stephen Walter Ranson will deliver the annual Samuel A Mathews lecture, March 9, at Loyola University School of Medicine. His subject will be "Cutaneous Sensation." The lecture is under the auspices of the Phi Beta Pi Fraternity.

The Tenth McArthur Lecture—Dr Samuel C Harvey, professor of surgery, Yale University School of Medicine, New Haven, will deliver the tenth Lewis Linn McArthur Lecture of the Frank Billings Foundation of the Institute of Medicine, March 23, at the Chicago Woman's Club. His subject will be "Reaction to Injury as a Function of Growth."

Program on Medical Illustration—"The Value of Medical Illustration to the Practitioner of Medicine" will be the subject of a symposium before the Chicago Medical Society, March 7. Speakers will include Dr Hollis E Potter, president, Chicago Roentgen Society, on "The X-Ray," W C Shepard, art department, Rush Medical College, "Historical Aspects of Medical Illustration," and Tom Jones, art department University of Illinois School of Medicine, "Modern Medical Illustrations." Dr Morris Fishbein, editor of THE JOURNAL, will discuss the papers. A dinner will be given in honor of the speakers before the meeting.

IOWA

Auxiliary Sponsors Health Essay Contest—The woman's auxiliary of the Iowa State Medical Society is sponsoring a health essay contest in the high schools throughout the state. Prizes are being offered to those students who write the best essays on "Health Our Greatest Asset—And How to Maintain It." The speakers' bureau of the state medical association is cooperating in this project, and the state department of public instruction has endorsed it. The contest closes March 15.

Society News—Dr Edwin P Sloan, Bloomington, Ill, discussed hypothyroidism before the Black Hawk County Medical Society, January 16—A symposium on acute abdominal conditions was presented by Drs Bush Houston, Nevada, and Albert I Haugen, Ames, before the Boone-Story County Medical Society in Boone, January 16—Dr Sylvester E Hinshaw, Newton, discussed "Sarcoma of the Mouth" before the Jasper County Medical Society, January 2, in joint session with the county dental society—Dr Charles W M Poynter, Omaha, addressed the Pottawattamie County Medical Society in Council Bluffs, February 1, on "Modern Trend of Medical

Education"—Speakers before the annual meeting of the Sioux Valley Eye and Ear Academy in Sioux City, January 23, included Drs Sydnor D. Maiden, Council Bluffs, on "Acute Laryngotracheobronchitis," and Dr Thomas R. Gittins, Sioux City, on "Biochemistry in Rhinolaryngology." Dr Charles L. Chambers, Des Moines, is president of the association.—At the meeting of the Upper Des Moines Medical Society in Emmetsburg, January 23, speakers included Drs Fred L. Knowles, Fort Dodge, on "Reduction of Fractures of the Neck of the Femur—Double Pin Method," and Joseph B. Priestley, Des Moines, "Surgical Management of Peptic Ulcer."

MARYLAND

Sanitation Program—A state-wide rural sanitation program has been inaugurated in Maryland with the state department of health and the U. S. Public Health Service cooperating. The state has been divided into four districts with a supervisor in charge in each district and a local supervisor handling the work in each county. Emphasis is placed on properties without sewerage facilities.

Clinics at University of Maryland—Dr. Lewellys F. Barker, Baltimore, conducted a medical clinic at the University of Maryland, February 1, the first in a series under the auspices of the division of medical extension. Dr. Charles R. Austrian conducted a medical clinic February 9, and Drs. Louis Hamman and Hugh R. Spencer a clinical pathologic conference, February 15. Dr. Louis P. Hamburger concluded the series, February 22, with a clinic on migraine.

CWA Supports Carbon Monoxide Research—Efforts to diminish the amount of carbon monoxide that is formed in automobile exhausts and to convert the gas already formed into less harmful products will be carried on in a survey under the supervision of faculty members of Johns Hopkins University, with funds provided by the Civil Works Administration. Twenty-one unemployed chemists will be engaged for the study, newspapers announced, and laboratories will be constructed in a wing of Remsen Hall.

Medical Milk Commission—Announcement is made of the formation of a state medical milk commission for the certification of milk and dairies in Maryland. The house of delegates of the Medical and Chirurgical Faculty of Maryland authorized the appointment of the commission following a recommendation of the state health department. The following physicians are members:

For Baltimore: Allen W. Freeman, chairman; James H. Mason, Jr.; Louis P. Hamburger; and Frederick B. Smith.
For Baltimore County: Frank W. Keating; Owings Mills: For Cecil County: Dr. Clarence I. Benson; Port Deposit: For Montgomery County: Jacob W. Bird; Sandy Springs.

MASSACHUSETTS

Pneumonia Collaborators—The study of pneumonia in Massachusetts, which is now in its fourth year, was extended into the area around Lawrence Dec. 19, 1933, with headquarters at the Lawrence General Hospital. Seven local physicians have been designated pneumonia "collaborators" who, when called by other physicians in suspected cases of lobar pneumonia, will undertake to have sputum or other material from the patient typed at once. An annual appropriation of \$36,200 for three years with a tentative agreement of support for an additional two years was granted by the Commonwealth Fund of New York in 1931. Since that time the experiment has been projected in seventeen selected areas of the state. The appropriation provides the cost of organizing the area, producing and distributing serum, maintaining a typing laboratory and training technicians from the outlying laboratories in the state in pneumococcus typing. The primary objective is to establish, if possible, whether or not pneumonia serum is a remedy for the treatment of pneumonia caused by certain types of pneumococci. If this can be determined, it is hoped that, when the Commonwealth Fund withdraws its support, the state will take over the production and distribution of bivalent antipneumococcus serum for cases of type I and type II lobar pneumonia and supply it to all physicians throughout the state without cost. No charge is made to the patient in the present study although the collaborator receives a consultation fee. In the instances in which patients are unable to pay, the Commonwealth Fund pays the collaborator. A fee is also charged in the laboratories, except the state bacteriologic laboratory in Boston, but, when patients cannot pay, hospitals will do the work without charge. Recently a new plan was introduced in an effort to determine whether physicians in general practice wish to use this serum. In communities adjacent to Boston and Newton any physician may obtain serum provided sputum or other material is sent from the patient to an approved labora-

tory and a type I or type II pneumococcus found, and that the physician is willing to state that his patient has not been ill with pneumonia longer than four days. The fact that only a relatively small amount of serum has been delivered in this manner is attributed to the little amount of publicity. The results obtained thus far in the study confirm previous work on concentrated serum for the treatment of pneumonia, making it positive that the use of this serum in cases of the proper type will save the lives of many patients. A special advisory committee supervises the work, and Dr. Roderick Heffron is field director.

MINNESOTA

Society News—The Hennepin County Medical Society will be addressed March 5, by Dr. Arthur Steindler, Iowa City, on "Treatment of Paraplegia in Tuberculosis of the Spine" and, March 7, by Richard E. Scammon, Ph.D., dean of medical sciences, University of Minnesota on "Indexes to Medical Literature."—Dr. Charles E. Connor, St. Paul, addressed the Minnesota Academy of Medicine, February 14, on "Sinusitis and Asthma." Dr. Paul A. O'Leary, Rochester, presented a thesis on "Disseminated Lupus Erythematosus."

Child Guidance Clinic Reorganized—Dr. Samuel Alan Chaffman has been appointed director of the Minneapolis Child Guidance Clinic, succeeding Dr. Herbert E. Chamberlain, who resigned last year to direct a similar clinic established at the University of Chicago. Reorganized to exist almost completely for the public school system the clinic has been vested with the responsibility for examining and passing on all candidates for the special classes of defectives. Dr. Chaffman recently of Denver, is a graduate of the University of Minnesota School of Medicine, Minneapolis.

MISSOURI

CWA Funds for Sanitation Program—Funds have been made available to carry on a program of sanitation in sixty counties of the state, under the auspices of the U. S. Public Health Service and the state board of health. Labor is being provided by the Civil Works Administration.

Society News—At a meeting of the Kansas City Academy of Medicine, January 19, Dr. William T. Peyton, Minneapolis, spoke on "Advancement in Diagnosis and Treatment of Malignant Disease."—The St. Louis Urological Society presented a symposium on hematuria before the St. Louis Medical Society, January 12, the speakers were Drs. John P. Altheide, Vincennes, Indiana; Leo Bartels and Joseph Hoy Sanford.—A symposium on cardiac arrhythmias was presented before the St. Louis Medical Society, January 19, by Drs. Drew W. Luten, Eugene Lee Shrader, John J. Hammond and Samuel B. Grant.—At a meeting of the Jackson County Medical Society, January 30, the speakers were Dr. Carl F. Nelson, Lawrence, Kan., on "Metabolism of Cholesterol and Other Blood Lipids" and Pearl L. Moorman, Joplin, and Dr. Ralph E. Duncan, Kansas City, "Use of Hydrochloric Acid Intravenously."—The Jasper County Medical Society was addressed January 30 by Drs. Charles C. Conover and Everett R. Deweese, Kansas City, on "Functional Disorders of the Colon from the X-Ray and Clinical Standpoint."—Dr. Edward P. Heller, Kansas City, spoke on "Modern Treatment of Fractures" before the Nodaway County Medical Society, February 7, and Dr. Ernest Kip Robinson, Kansas City, "Avoiding Complications in Gynecological Radium Therapy."—Dr. Julius Frischer, Kansas City, addressed the Randolph County Medical Society at Moberly, January 9, on "Transurethral Electrosurgery of the Prostate."—Dr. LeRoy Sante was among the speakers before the St. Louis Traders Club, February 1, on observations on the use of iodized oil in chest diagnosis.

NEBRASKA

Nebraska University News—Dr. John Jay Keegan has recently been appointed chairman of the department of surgery, University of Nebraska School of Medicine, Omaha, to succeed the late Dr. Byron B. Davis, and Dr. Rodney W. Bliss, acting chairman of the department of internal medicine to succeed Dr. Edson L. Bridges. The department of physiology and pharmacology has received a grant of \$1,800 from the Frederick Stearns Company for investigation under the direction of Drs. A. Ross McIntyre, professor of pharmacology, and Ernest L. MacQuiddy of the department of internal medicine.

Society News—A symposium on acute rheumatic fever and its sequelae was presented before the Omaha-Douglas County Medical Society, February 27, by Drs. John Harry Murphy, Edson L. Bridges, Barney M. Kully, and Benjamin Carl Russum.—Drs. Frank P. Murphy, Omaha, and Ralph H. Lukart

addressed the Otoe County Medical Society, Nebraska City, February 12, on obstetric problems of the general practitioner.—Dr Mason E Lathrop, Wahoo, addressed the Dawson County Medical Society, Gothenburg, January 8, on "Decentralization of Medicine"—Three Lincoln physicians addressed the Madison Six Counties Medical Society, Norfolk, January 16, as follows: Drs Roscoe L Smith, on "600,000 Volt X-Ray Therapy", Clayton F Andrews, "Diseases of the Thyroid Gland," and George W Covey, "Pneumonia"

NEW HAMPSHIRE

Personal—Dr Fred E Clow, Wolfeboro, was elected president of the newly organized New England Association for the Study of Neoplastic Diseases, Dec 13, 1933, in Manchester

NEW YORK

University News—Syracuse University College of Medicine has discontinued its department of obstetrics in order to concentrate all its work in Syracuse Memorial Hospital. This action was taken in accordance with the policy of the school's affiliated hospitals in avoiding duplication in connection with their cooperative development

Society News—The Central New York Dermatological Society, which was organized in June 1933, held its first scientific session at Utica, January 4. Dr Lopo de Mello, Syracuse, was made secretary.—Dr Harold E B Pardee addressed the Medical Society of the County of Nassau, Mineola, January 30, on "The Failing Heart of Middle Life"—The eastern section of the American Laryngological, Rhinological and Otological Association held a meeting in Rochester, January 5, with the following speakers: Drs Harris P Mosher, Boston, on "Treatment of Osteomyelitis of the Frontal and Maxillary Sinuses", Frederick M Law, "Otitic Meningitis—Errors of Interpretation in X-Ray of Accessory Nasal Sinuses," and Samuel J Crowe, Baltimore, "Experimental Evidence of Sound Waves"—Dr Joseph W Moore, Albany, chairman, state parole board, addressed the Medical Society of the County of Albany, January 24, on "Medical Aspects of Crime"

New York City

Sixth Harvey Lecture—The sixth Harvey Lecture of the season will be delivered at the New York Academy of Medicine, March 15, by Dr George L Streeter, director of the department of embryology, Carnegie Institution of Washington, Baltimore, on "The Significance of Morbid Process in the Fetus"

The Coordinating Council—The coordinating committee of the five county medical societies in New York, composed of three representatives from each society, entertained Dr John L Rice, newly appointed health commissioner, at dinner at its January meeting discussing problems of medicine in relation to the department of health. The committee changed its name to the "Coordinating Council" and elected Dr David J Kaliski, chairman

Dr Hartwell Chosen Director of Academy—Dr John A Hartwell has been appointed director of the New York Academy of Medicine to succeed the late Dr Lunsly R Williams. Dr Hartwell, who was president of the academy from 1929 to 1933, acted as interim director during Dr Williams' illness. After graduating from Yale University School of Medicine, he began practice in New York in 1893. Since 1910 he has been associate professor of surgery and clinical professor of surgery at Cornell University Medical School

Society News—Dr Percy S Pelouze, Philadelphia, addressed the Association of Italian Physicians in America, January 15, on "Gonorrhea in the Male". Dr Angelo M Sala is president of the society.—Drs Elaine P Ralli and Alice M Waterhouse addressed the Women's Medical Association of New York, January 10, on "Blood Concentration in Diabetic Coma"—Drs William F MacFee and Robert R Baldrige addressed the New York Surgical Society, January 10, on "Physiological Considerations Related to the Infusion Treatment of Shock"—Drs Cornelius P Rhoads and Thomas T Mackie addressed the Medical Association of the Greater City of New York, January 12, on clinical aspects of sprue and amebiasis, respectively. Drs Theodore J Curphey and Jesse G M Bullock addressed the association, February 9, on "Laboratory Management of Pneumonia" and "Pneumonia Due to Pneumococcus Type 8 (Cooper), Its Occurrence, Characteristics and Treatment with Its Specific Serum," respectively.—Dr Henry W E Walther, New Orleans, addressed a joint meeting of the New York Society of the American Urological Association and the section of genito urinary sur-

gery of the New York Academy of Medicine, January 17, on "Clinical Evaluation of Dye Therapy in Urinary Infections"—Dr George G Ornstein addressed the Medical Society of the County of Queens, January 30, on differential diagnosis of pulmonary diseases, and Dr David J Kaliski discussed the relation of physicians to the Civil Works Administration

NORTH CAROLINA

Society News—The Third District Medical Society met jointly with the Sampson County Medical Society in Clinton, December 15, with the following speakers, among others: Drs David Russell Perry, Durham, "When Surgical Procedure Is Advisable in Pulmonary Tuberculosis", George M Cooper, Raleigh, "High Maternal and Infant Mortality in North Carolina," and Ernest S Bullock, Wilmington, "Injuries to the Head"—Physicians of Avery County reorganized the Avery County Medical Society in December, with Dr Ronda H Hardin, Banner Elk, as president, and Burruss B McGuire, Newland, secretary.—Dr Wingate M Johnson, Winston-Salem, addressed the Mecklenburg County Medical Society, Charlotte, January 2, on "The Case Against State Medicine"

OHIO

Cincinnati Health Officer Retires—Dr William H Peters, health commissioner of Cincinnati since 1918, has retired because of ill health. Dr Peters entered the health department in 1912 as chief medical inspector, shortly after his graduation from the University of Cincinnati College of Medicine. Dr Owen C Fisk has been acting health commissioner since Dr Peters became ill last October

Dr Wolfstein Honored—Dr David I Wolfstein, Cincinnati, was guest of honor at a reception given by his family and friends on his seventy-second birthday, January 11, when he announced his retirement from medical practice. Dr Wolfstein, a native of Hannibal, Mo., was graduated from the Medical College of Ohio in 1888. For many years he was professor of mental diseases at the University of Cincinnati College of Medicine and served on the staffs of the City, General, Jewish and Speers hospitals. He began practice in Cincinnati forty-two years ago and has frequently taken an active part in civic affairs

Society News—Dr Evarts A Graham, St. Louis, addressed the Cincinnati Academy of Medicine, February 26, on "Fads and Fancies in the Treatment of Acute Empyema"—A symposium on arthritis and rheumatism was presented before the Montgomery County Medical Society, February 16, by Drs Thomas E Newell, Jerome Hartman and Sterling H Ashmun, Dayton.—Dr Douglas Quick, New York, addressed the Academy of Medicine of Toledo and Lucas County, February 9, on "Malignant Diseases of the Upper Mucous Membrane Tract"—Dr Alfred P Hancuff, Toledo, addressed the Sandusky County Medical Society, Fremont, January 25, on "Diagnosis and Management of Pelvic Inflammatory Disease"—Dr Arthur C Bachmeyer, Cincinnati, addressed the annual joint meeting of the Miami and Shelby county medical societies, Piqua, January 5, on medical economics.—Drs Ernest Perry McCullagh, Cleveland, and George J Waggoner, Ravenna, addressed the Portage County Medical Society, Ravenna, February 1, on "Research in Endocrinology" and "Legislation and the Doctor," respectively.—Dr Alfred W Adson, Rochester, Minn., addressed the Dayton Academy of Medicine, February 2, on "Surgery of the Vegetative Nervous System"—Dr Ralph K Updegraff, Cleveland, addressed the Lorain County Medical Society, January 9, on the electrocardiograph.—Dr Richard D Giff Wheeling, W Va., addressed the Tuscarawas County Medical Society, January 11, on "Recent Advances in Treatment of Genito-Urinary Disease"—Dr Max M Zimninger, Cincinnati, discussed surgical tuberculosis of the chest at a meeting of the Hempstead Academy of Medicine, January 8

PENNSYLVANIA

Monthly Graduate Assembly—The third monthly graduate assembly at the Geisinger Memorial Hospital, Danville, January 26, under the auspices of the Montour County Medical Society, was devoted to a symposium on urology. Dr Harold L Foss conducted an operative clinic and the following guests took part in the scientific program: Drs Hugh H Young, Baltimore, Thomas C Stellwagen, Jr, Theodore R Fetter and Percy S Pelouze, all of Philadelphia. Drs Henry F Hunt and Carl E Ervin of the hospital staff also presented papers on urologic subjects. Dr Robert Y Grone was chairman.

Society News—Dr William F Rienhoff, Baltimore, addressed the Lackawanna County Medical Society, Scranton, February 6, on hyperthyroidism, Dr Isidor S Ravdin, Phila-

delphia, spoke, January 23, on "Use and Abuse of Fluids" At the request of the mayor of Scranton the society recently appointed a committee of twelve physicians to act in an advisory capacity to the department of health. A central bureau for the collection of convalescent serums from cases of scarlet fever and poliomyelitis has been established and it is planned to make available also serums for treatment of measles and epidemic encephalitis.

Philadelphia

Potter Lecture—The William Potter Memorial Lecture of Jefferson Medical College was delivered by Dr Charles R. Stockard, professor of anatomy, Cornell University Medical College New York, March 1, on "The Genetic Basis and the Internal Secretions in Growth Types and Body Form."

Lectures on Ophthalmology—Dr Alfred Bielschowsky, professor of ophthalmology, University of Breslau, will deliver a series of lectures at the Wills Eye Hospital, March 20-23 on physiology and pathology of ocular muscle paralysis and the more unusual forms of concomitant squint. The fee will be \$10 and the course will be limited to forty applicants.

Joint Surgical Meeting—The Philadelphia Academy of Surgery had as guests the members of the New York Surgical Society at its meeting, February 14. Speakers were Drs Edward J. Klopp, on "Sarcoma of the Small Intestine," George P. Muller, "Subclavian Aneurysm," DeForest P. Willard, "Treatment of Compression Fractures," Eldridge L. Larson, "Perforation in Acute Cholecystitis," and Charles H. Frazier, "Surgical Management of Chronic Subdural Hematoma."

TENNESSEE

Health at Nashville—Telegraphic reports to the U. S. Department of Commerce from eighty-six cities with a total population of 37 million for the week ended February 17 indicate that the highest mortality rate (247) appears for Nashville, and the rate for the group of cities as a whole was 136. The mortality rate for Nashville for the corresponding period last year was 178, and for the group of cities, 124. The annual rate for eighty-six cities for the seven weeks of 1934 was 126, as against a rate of 127 for the corresponding period of the previous year. Caution should be used in the interpretation of these weekly figures, as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have a large Negro population may tend to increase the death rate.

Society News—Dr Gilbert Madison Roberts addressed the Chattanooga and Hamilton County Medical Society, December 16, on transurethral resection of the prostate. Speakers before the Carroll-Henry-Weakley Counties Medical Society at McKenzie, December 14, were Drs George K. Carpenter, Nashville, on injuries to the back, Willis C. Campbell, Memphis, fractures of the leg, and Peter Whitman Rowland, Jr., Memphis, treatment of traumatic shock. Drs Henry M. Cass and Carroll H. Long addressed the Washington County Medical Society, January 4, on diseases of the rectum and biologic tests for pregnancy, respectively. Drs Harold D. Long, Chattanooga, and Walter S. Moore, Etowah, addressed the McMinn County Medical Society, Athens, January 11, on "Acute Infectious Diseases of Childhood" and "Complications of Influenza," respectively. Speakers at the meeting of the Shelby County Medical Society, Memphis, November 21, were Drs William Battle Malone, on "The Advisability of Having a Fee Schedule," Lucius C. Sanders, "The Economic Problem of Modern Practice" and Henry G. Rudner, "Is State Medicine Necessary?" Dr Charles D. Lucas, New York, addressed the Knox County Medical Society, Knoxville, December 5, on cancer.

TEXAS

Personal—Dr Hugh Leslie Moore, Dallas, was honored with a banquet given by the Dallas County Medical Society and the Women's Auxiliary at the Dallas Country Club, January 5, in recognition of his recent election as president of the Southern Medical Association. Dr William T. Shell, Jr., has been appointed health officer of Corsicana, to succeed the late Dr Walter D. Cross.

Society News—Drs Tate Miller and Oscar M. Marchman addressed the Dallas County Medical Society, Dallas, January 22, on "Medical Treatment of Cholecystitis," and "Anatomy and Development of Paranasal Sinuses," respectively. Drs Robert M. Barton and Cleve C. Nash, Dallas, addressed the Lamar County Medical Society, Paris, January 4, on treatment of anemias and head injuries, respectively. Drs Julius A. Heyman, Wichita Falls, and Fred Hudson, Stamford, addressed

the Wichita County Medical Society, Wichita Falls, January 9, on "Relief of Intractable Pelvic Pain by Sympathectomy," and "An Outbreak of Typhus Fever in West Texas," respectively.

VIRGINIA

Dr McGuire Honored—Dr Stuart McGuire, eminent professor of surgery, Medical College of Virginia, Richmond, was the guest of honor at a dinner given by the faculty of the college in recognition of his forty years of continuous service to the school, January 15, at the Commonwealth Club of Richmond. Dr Roshier W. Miller, who has also been connected with the college for forty years, presided, and tributes were paid to Dr McGuire by the following speakers: Drs Robert C. Bryan, Clifton M. Miller, Joseph F. Geisinger, Douglas Vanderhoof and James Allison Hodges, William T. Santer, L.L.D., and Mr J. R. McCauley, all of the college staff; J. Fulmer Bright, mayor of Richmond, and Mr William P. Miller, member of the board of visitors. At the close of the program Dr Singer presented to Dr McGuire a silver platter on behalf of the faculty.

WEST VIRGINIA

Society News—Dr Roy Benson Miller, Parkersburg, president, West Virginia State Medical Association, addressed the Monongalia County Medical Association, January 2, on medical economics. Dr Walter E. Vest, Huntington, addressed the Academy of Medicine of Parkersburg, January 4, on "The Relationship of Gallbladder Disease to Cardiac Pain." Drs Stephen A. Cunningham, Marietta, Ohio, and Richard D. Gill, Wheeling, addressed the Tyler-Wetzel Counties Medical Society, New Martinsville, January 16, on "Thyroiditis and 'Ureteral Obstructions,'" respectively. Dr Desautour G. Preston, Lewisburg, presented a paper on Rocky Mountain spotted fever, Eastern type, before the Greenbrier Valley Medical Society, Ronceverte, December 12.

GENERAL

Brinkley's Mexican Radio Station Closed—The department of communications of the Mexican government forcibly closed radio station XER at Villa Acuna, Mexico, across the border from Del Rio, Texas, February 24, according to the *Chicago Tribune*. The government charged that the station, which is owned by John R. Brinkley, "goat gland specialist" of Milford, Kan., had "persistently and constantly refused to obey broadcasting regulations, had used English exclusively and transmitted by remote control from the United States medical and hygienic talks and advertised medical articles without authorization." It was said the statement issued by the government said also that the station has displayed "an attitude of open rebellion" and was "of no benefit to the country." Thirty days will be allowed for the station to dismantle its equipment, according to the newspaper report, if this order is not carried out government engineers will remove the machinery.

Conference on the Handicapped Child—A conference on the education and rehabilitation of handicapped children will take place at New York University, New York, March 9-10. The session is sponsored by the National Council on the Physically Handicapped, the National Committee for Mental Hygiene and the university. Section meetings dealing with the problems of given types of handicapped children are each under the auspices of a national organization, with the following societies participating:

- International Society for Crippled Children
- National Rehabilitation Association
- American Occupational Therapy Association
- National Society for the Prevention of Blindness
- American Foundation for the Blind
- American Federation of Organizations for the Hard of Hearing
- National Education Association, department of lip reading
- National Association of the Deaf
- National Tuberculosis Association
- American Heart Association
- American Orthopsychiatric Association
- American Society for the Study of Disorders of Speech
- Child Study Association of America
- American Association for the Study of Mental Deficiency
- National Conference of Juvenile Agencies
- American Association of Visiting Teachers

This conference has been called in the hope that it will provide an opportunity to arouse public interest not only in the New York area but over the country as well in the educational problems of the handicapped child and thereby counteract somewhat the tendency of cuts in educational budgets to bear most heavily on the handicapped.

Interstate Quarantine Regulations Amended—All birds in the psittacosis family offered or accepted for shipment in interstate traffic must be accompanied by a certificate from the

Government Services

General Gilchrist Retires

Major Gen Harry L Gilchrist, chief of the Chemical Warfare Service, U S Army, from 1929 to 1933, retired from active service, January 31, having reached the age of 64 on January 16. General Gilchrist was born in Iowa in 1870. He graduated from Western Reserve University School of Medicine in 1896 and entered the Army Medical Corps two years later. He organized a field hospital following the San Francisco earthquake in 1906. In 1917, General Gilchrist was placed in command of Base Hospital No 4, organized from Western Reserve University, the first unit of American troops to go to Europe. As British General Hospital No 9 at the front, the unit was commanded by General Gilchrist until December 1917, when he was made medical director of the Chemical Warfare Service with the American Expeditionary Forces. After the end of the war he was in command of the American Typhus Relief Expedition to Poland, where he remained for two years during the war of Poland with the Bolsheviks. In 1929 he was appointed chief of the Chemical Warfare Service, a position he held until May 26, 1933. General Gilchrist is one of four officers of the Medical Corps who have been assigned to military duties as general officers and chiefs of branches outside the medical department. Many decorations have been bestowed on him, including the Distinguished Service Medal and Victory Medal with nine clasps, from the United States, General Service Medal and a citation for gallantry in the British Army, and Officer of the Legion of Honor of France.

Annual Report of Surgeon General of Army

The health of the U S Army was satisfactory during the year 1932, according to the annual report of the surgeon general. The average daily strength for officers and enlisted men, excluding nurses, was 131,925, a reduction from 135,425 for 1931. A new low rate for venereal diseases (42 per thousand) was established. However, this group of diseases still heads the list as a cause of lost time from duty. There were 5,539 admissions, 81 discharges for disability, and 220,395 days of lost time attributed to these diseases. Automobile fatalities head the list of causes of death for the third year, although there was a reduction in 1932, 73 as compared with 92 for the previous year. During the preceding twenty years, exclusive of the abnormal years 1917-1919, suicide was the leading cause sixteen times and tuberculosis, four times. During 1932 suicide stood second with sixty-six deaths. Tuberculosis, however, stood seventh on the list with twenty-nine deaths. The admission rate for all causes was 651, slightly lower than in 1931. A total of 567 deaths occurred during the year as compared with 626 during 1931. For the first time on record the deaths among officers and enlisted men from accidents (284) exceeded the deaths from disease (279). There were 1,471,147 days lost during the year on account of sickness and injury. The non-effective rate of 30.5 was lower than the rate of 32.5 for 1931. The average number of days lost per patient was 17.1 as compared with 18.1 during the previous year. The average number of patients in hospitals each day of the year was 6,627. In addition, 1,019,654 outpatients were treated. Of the 6,627 hospital patients, 58.19 per cent were army personnel and 30.12 per cent were beneficiaries of the Veterans' Administration. The cost of hospitalization per patient day in the four general hospitals and the station hospital, Fort Sam Houston, fell to an average of \$4.745 as compared with \$5.03 for 1931. There were 180,115 vaccinations administered and 292,202 physical examinations made. Two new hospitals were opened during the year and six were closed. In 1932, 69 officers and 1,497 enlisted men were discharged as physically or mentally disqualified. Diseases of the cardiovascular and nervous systems continue to be the major factors in reasons for discharge. In 1932 there were 31,287 admissions from respiratory diseases with a rate of 237.2, the highest for several years. Influenza led the causes of admission for the entire army with a rate of 66.4 per thousand, gonorrhea was second, 25.4, and syphilis third, 11.9. One death occurred among 616 cases of malaria as compared with one death among 868 during the previous year. The lowest admission rate for tuberculosis in the last decade was reached (2.2). On the last day of the fiscal year there were 6,523 enlisted men enrolled in the medical department, as compared with 6,528 at the beginning of the year. No new enrolments were permitted in the Reserve Officers Training Corps units of the medical department under a proviso in the army appropriation bill for 1933.

state health officer stating that they came from an aviary or other distributing establishment which, after examination, was found to be free from infection, in accordance with recent amendments to the U S Interstate Quarantine Regulations of the Public Health Service. The certificate accompanying the birds must be surrendered to the health authorities at the destination of the shipment. No bird of the species that is under 8 months of age shall be offered or accepted for shipment or transport in interstate traffic. Another amendment lists the following diseases regarded as contagious and infectious, for the purpose of interstate quarantine: plague, cholera, smallpox, typhus fever, yellow fever, typhoid fever, paratyphoid, dysentery, pulmonary tuberculosis, leprosy, scarlet fever, diphtheria, measles, whooping cough, epidemic cerebrospinal meningitis, anterior poliomyelitis, Rocky Mountain spotted or tick fever, syphilis, gonorrhea, chancroid, anthrax, influenza, pneumonia, epidemic encephalitis, septic sore throat, rubella, chickenpox and psittacosis.

Medical Bills in Congress—Changes in Status H R 7527, continuing the Civil Works program, has been approved by the President (Public No 93). It extends the provisions of the Federal Employees Compensation Act to employees of the Civil Works Administration only for disability or death resulting from traumatic injury while in the performance of duty, subject to certain conditions and limitations. Traumatic injury is declared to be only injury by accident causing damage or harm to the physical structure of the body. It does not include a disease in any form except diseases resulting naturally from the injury. S 2660 has passed the Senate, to regulate broadcasting from a studio located in the United States to be transmitted to a radio station in a foreign country whose emissions are received consistently in the United States. H R 7800 is the companion bill in the House. *Bills Introduced* S 2800, introduced by Senator Copeland, New York and S 2858, introduced (by request) by Senator McCarran, Nevada, propose to prevent the adulteration, misbranding and false advertising of food, drugs and cosmetics. S 2865, introduced by Senator Walsh, Massachusetts provides that all officers now in the Dental Corps of the Navy who entered service prior to July 1, 1918, who prior to that date had not attained such minimum age as to provide for their eligibility for appointment to the Dental Corps of the Navy, and whose active service has been continuous, shall, for purposes of precedence, be credited with their total active commissioned service. H R 7747, introduced by Representative Burke, California, proposes to provide a pension for blind veterans of the military and naval services in the United States. H R 7749, introduced by Representative McKeown, Oklahoma, proposes to provide pensions for the aged, needy blind and those totally incapacitated for work. H R 7756, introduced by Representative Chase, Minnesota, proposes to reenact legislation conferring benefits on veterans that was repealed by the act of March 20 1933. H R 7762, introduced by Representative Sadowski, Michigan, proposes a federal appropriation for allotment to the several states for the "relief" of the aged. H R 7797, introduced by Representative Koppelman, Connecticut, proposes to authorize the payment of claims for unauthorized emergency treatment of World War veterans. H R 7853, introduced by Representative Lozier, Missouri, and H R 8092, introduced by Representative McSwain, South Carolina, propose to confer additional benefits on veterans. Among other things, the bills provide that any World War veteran employed in the active military or naval service between April 6, 1917, and Nov 11 1918, not dishonorably discharged, suffering from disability, disease or defect, who is in need of hospitalization or domiciliary care, and is unable to defray the necessary expenses therefor, shall be furnished such necessary hospitalization or domiciliary care in any Veterans' Administration facility, within the limitation of such facilities, irrespective of whether the disability was due to service. A statement by the veteran that he is unable to defray the expenses necessary for hospitalization or domiciliary care must be accepted by the Administrator of Veterans Affairs as conclusive evidence of that fact. H R 7862 introduced by Representative Disney, Oklahoma proposes to reenact all legislation conferring benefits on veterans of the Spanish-American War, including the Boxer rebellion and the Philippine insurrection that were repealed by an act passed March 20 1933. H R 7868, introduced by Representative Lozier, Missouri, proposes to grant pensions and increases of pensions to certain soldiers, sailors, and nurses of the war with Spain the Philippine insurrection, or the China relief expedition, and their widows and dependents. Pensions for contract nurses are provided for under existing law. No pension is provided under existing law or in the proposed bill for contract surgeons.

Effects of Diet on the Teeth

Since 1917, May Mellanby (wife of the physiologist Edward Mellanby) has been continuously engaged in researches for the Medical Research Council on the effects of diet on the structure of the teeth and on dental disease. She has already published two reports (reviewed in *THE JOURNAL*) dealing with experimental work on animals, which showed the nutritional and environmental conditions that control the formation of healthy teeth and jaws. A third report, entitled 'The Effect of Diet on Dental Structure and Disease in Man,' has just been published and completes work which the Medical Research Council describes as marking a definite advance in knowledge of the causes and prevention of dental decay. It raises nutrition above oral hygiene as the chief means of protecting the teeth. Mrs. Mellanby has shown that the liability of a tooth to decay depends largely on the perfection of its structure, which in turn depends on nutritional influences during growth both antenatal and postnatal. Ill formed (hypoplastic) teeth are much more common than has been supposed and are particularly liable to bacterial invasion. The teeth require for their formation adequate supplies of calcium and phosphorus and an ample supply of vitamin D to insure that these are put to use. The same factors are necessary for the health of the teeth during the rest of their lives, and especially for the healing of caries. Thus two main factors control the onset of caries: the better formed the teeth the more resistant they are, and, independent of structure, resistance is directly influenced by diet.

Prolonged studies of children's teeth have confirmed the views formed by Mrs. Mellanby from her investigations in young animals—that the health of the teeth can be largely controlled by certain dietary constituents, some of which are protective and others harmful. Prominent among protective substances is vitamin D (found in egg yolk, animal fat, milk, and cod liver oil). Cereals, such as oatmeal and bread, are given as the best example of harmful foods. Mrs. Mellanby has shown that perfectly calcified and regularly arranged teeth can be produced by including in the maternal diet during pregnancy and lactation, and in the diet of the offspring during dental development, substances containing much fat soluble vitamin, calcium and phosphorus, such as milk, egg yolk, fish and animal fats. The vitamin D can be obtained also by exposure of the skin to sunlight or other sources of ultraviolet radiation. Cereals, especially those rich in embryo, such as oatmeal, tend to produce badly developed (hypoplastic) teeth and call for a corresponding larger supply of calcifying foods for good development. The teeth of the majority of children in the British Isles are imperfect in structure and have a roughish surface, which predisposes them to caries. But resistance to caries can be increased independently of their original structure by a diet of high calcifying activity. Another fact demonstrated was that deficiency of vitamin A or carotene played an important part in the development of the periodontal tissues and in the control of the onset of periodontal disease, including pyorrhea.

In order to reduce the incidence of dental disease, especially in temperate zones, large changes must be introduced into the diets of pregnant and lactating women, infants and children during the whole period of dental development and, indeed, during the whole of life. The consumption of milk, eggs, cheese, animal and fish fats, potatoes and other vegetables must be

greatly increased and the consumption of cereals correspondingly diminished and, for the very young, abolished. Breast feeding must be general and prolonged even up to a year or more, provided a supplementary diet is given after about 6 months, which should include some iron and vitamin C. Cod liver oil or some other source of fat soluble vitamins should be given to all infants and children. If these instructions are followed, more perfect teeth will be formed and they will be more regularly arranged in well grown jaws. The teeth will better resist bacterial invasion, and both dental caries and pyorrhea should cease to be the scourge they are at the present time.

Obstetric Diploma for Practitioners

The recently established British College of Obstetricians and Gynecologists has for one of its main objects the improvement of the standard of midwifery among general practitioners who hold obstetric appointments in hospital or under public health authorities. As the result of three years' experience of its examination committee, the college has come to the conclusion that the present training of students in obstetrics is not sufficient to fit them for such responsible work and has decided to award a diploma (DCOG) to physicians who have had special postgraduate training and experience in obstetrics and satisfy their examiners. The membership of the college is a different matter and is confined to those who aspire to be specialists in obstetrics and gynecology. It requires a larger and wider experience than is possible for physicians engaged in family practice. Many candidates for the membership have been rejected because of insufficient training and experience, and they have reached a stage of their career in which they can no longer undergo such training. It is suggested that many of them will be suitable candidates for the diploma.

The Serum Treatment of Cerebrospinal Fever

In 1932 the ministry of health issued a memorandum on the serum treatment of cerebrospinal fever, making the following recommendations: 1. As soon as the patient is suspected on clinical grounds to be suffering from cerebrospinal fever, lumbar puncture should be performed and serum injected intrathecally without waiting for bacteriologic confirmation. 2. The dose should be about 30 cc of ordinary or 10 cc of concentrated serum. 3. The injection should be repeated every twenty-four hours for at least three or four days or until convalescence is obvious. The ministry has now received reports of 811 cases treated in this way. The case mortality was 26.9 per cent, which is considered encouraging. The inquiry is still proceeding and physicians are invited to send records on the forms provided by the ministry in all cases that are notified.

Tubercle Bacilli in Milk

The extent to which tubercle bacilli are found in the London milk supply was recently reported (*THE JOURNAL*, Nov 23, 1933, p 1737). Despite the fact that about 90 per cent of it is pasteurized, 32 per cent of samples purchased over the counter were found to contain tubercle bacilli. Comparison with an investigation made in Scotland, published by the Medical Research Council, is instructive. The inquiry covered the Scottish cities of Edinburgh, Glasgow, Aberdeen and Dundee. Composite churn samples of raw milk from individual farms were infected to the extent of 10 per cent, while raw tank (the tank for transport of milk, contains thousands of gallons) milk gave a figure of 37.5 per cent, flash pasteurized milk 8.2 per cent, and milk pasteurized by the holding process 2.8 per cent. Milk as retailed gave a figure over 5 per cent. The positive results for pasteurized milk were due to faults in the process, in some instances the result of improper design of the plant, in others to inefficient procedures. The tests for infection were performed by inoculation of guinea pigs. The higher percent

age of infection of milk in Scotland than in England (5 against 3.2) is in keeping with the higher incidence of bovine tuberculosis in the former. In England 45 per cent of the tuberculosis of the cervical glands, 48 per cent of lupus, 30 per cent of tuberculosis of the meninges and 18 per cent of that of bones and joints have been found to be due to the bovine bacillus. In Scotland the corresponding figures are 73, 53, 13 and 42.

Inquiry Into the Conditions of Midwifery

While the general mortality of the country and the mortality of most diseases have declined considerably in recent years, the mortality of childbirth has remained stationary. The government has therefore appointed a committee on midwifery to inquire into such questions as the overcrowding of the midwifery profession, leading to unemployment, the payment of the midwife's fee in necessitous cases, and the preparation of a pension scheme to enable midwives to retire at a suitable age. The chairman of the committee is the Earl of Athlone, and a number of leading politicians and obstetricians and members of the Midwives' Institute are included. The obstetricians represent the British College of Obstetricians and Gynecologists and are Dr T. Watts Eden, Dr J. S. Fairbairn and Mr L. C. Rivett.

Unreliable Mortality Statistics

The statistics on the causes of death, as prepared on the basis of certificates filed in the town halls, are highly unsatisfactory, a fact that is deplored every year at the sessions of the *Congrès d'hygiène*. The figures in these statistics cannot be a basis for information of medical importance. Only the diagnoses furnished in case of death by the hospitals and the clinics have a real value. The totals furnished for all of France, as derived from registrations in the town halls, are absolutely unreliable. Mr Marcel Moine, a specialist in medical statistics and a member of the *Comité national de défense contre la tuberculose*, in an article points out the defects in the registration of causes of death, which he regards as unworthy of a large civilized country. There has been some improvement since, in 1925, the *Office national d'hygiène* began its special study of vital statistics. Until then, one fifth of the deaths were designated as being due to unknown cause. In 1930 one death out of eight failed to show the special cause. After age 50, senility is frequently given as the cause of death, without other details. It is certain that chronic bronchitis given in young adults as the cause of death conceals many cases of tuberculosis. The care given to these certifications varies. In the department of the Seine (Paris) only 2 per cent of the deaths fail to show the actual cause, in the department of Lozère, 55 per cent of the deaths are registered without a statement as to the cause. The visit, required by law, of the physician who confirms the death does not furnish the needed information for the reason that the attending physician failed to report the cause of death, often for fear of embarrassing the family of the deceased. It is impossible to secure accurate statistics on deaths from tuberculosis, cancer, syphilis, cerebral softening and the like. In many small communes, death is not even confirmed by a physician and the registration bureau accepts in such cases the declaration made by the family.

The Destiny of Infectious Diseases

Prof Charles Nicolle who has resigned from the Pasteur Institute of Tunis, where he has been more than twenty years, to become a professor in the *Collège de France* has published a book entitled 'The Destiny of Infectious Diseases'. In answering the problem "In generations to come, what will become of our present infectious diseases—in man as well as

animals?" he starts with the premise that all diseases, aside from physical forces and chemical agents, are due to the action of living organisms. With respect to these infectious agents, one is entitled to assume an origin and an end. Have all infectious diseases always existed and will they always exist? Perhaps diseases now confined to limited areas of the earth will finally invade other lands, as a result of rapid means of communication. Micro organisms adapt themselves to new conditions if possible, and they degenerate if the environment becomes too hard. Some changes, as in the higher animals, may become fixed. Other changes may be unstable and reversible. If the virulence is influenced by a transformation, one can explain thus the variable gravity of epidemics. The crusade that mankind carries on against micro-organisms causes them gradually to develop greater resistance. It may be observed that they become less vulnerable to various antiseptics and even to serums, as these become more generally employed in civilized communities. The increasing gravity of diphtheria, in all countries, furnishes a good example of this phenomenon. Then, too, one can count on the disappearance of certain diseases owing to the gradual suppression of the animals that serve to transmit them. It is possible, also, that man will develop a greater resistance to micro-organisms, which resistance will become fixed by heredity.

Leprosy in French West Africa

From a report presented by Mr Gaston Joseph to the *Office d'hygiène publique*, it appears that the crusade against leprosy has entirely renounced the system of permanent internment of lepers even though this system rescued Europe from leprosy in the Middle Ages. To the modern hygienist, permanent isolation appears inhuman, and useless, in view of the present status of medical science. Today in French West Africa the basis of control is the preparation of a list of all lepers, obtained through the aid of physicians, by information collected through sanitary agents, and by other means. If, after a laboratory examination, the diagnosis of leprosy is confirmed, the name of the patient is added to the special lists. If the patient is found to be non-contagious he is given ambulatory treatment and comes every week for inspection. He lives in a house by himself and no one is allowed to use his cooking utensils or any of his belongings. He must notify the authorities if he leaves home for a certain length of time. If on examination he is found to be contagious (open leprosy), he is hospitalized either in an isolated ward of a nearby hospital or at the Central Institute of Leprosy at Bamako. After prolonged treatment and reexamination, if he is no longer contagious, he is admitted to ambulatory treatment. If he is found to be incurable, he is sent either to a village-sanatorium or to the Central Institute of Leprosy. In this institute, which is in process of construction, the patients are grouped according to race, and their surroundings are made to resemble their native homes. There is a nursery, where the children of leprous mothers being treated in the institute are cared for, and a research laboratory. The institute will be in charge of a medical specialist.

Protest Against Free Consultation Centers

At a recent meeting of the *Fédération des syndicats médicaux de la Seine*, protests were raised against the creation of absolutely free consultation centers in the dispensaries, which are increasing in number, being organized in Paris by the administration of the *Assistance publique*. It was emphasized at this session that the medical profession pays annually, to the city of Paris, from twelve to fifteen million francs (\$720,000-\$900,000) in the form of professional taxes, and that as taxpayers, physicians help to pay the cost of this demagogic generosity, to the detriment of their own profession. The federation passed a resolution that barbitol compounds, which are causing an increasing number of fatal poisonings, be not dispensed without a medical prescription.

Restrictions on the Number of University Students

The question of applying vigorous measures to lessen the number of students matriculating each semester for university studies has been much discussed (*THE JOURNAL*, July 22, 1933, p 295). Germany has decided to attack the problem of overcrowded academic professions with a drastic remedy. For the year 1934, the number of pupils of secondary schools allowed to take up university studies on graduation will be limited to 15,000. Of this number, approximately 9,000 have been allotted to Prussia. Bavaria has been allotted 1,670, Lubeck only 34, and Schaumburg-Lippe, the smallest unit of the reich, only 12. The number of places delegated to women students is 10 per cent, which signifies a marked restriction of female students. The total number of women students is to be further limited from year to year, the present age groups date back to the war period and hence are not so well represented as they would be otherwise. Moreover, it is planned in the future to reduce the number of pupils attending the secondary schools and particularly the upper classes, so that the application of restrictions to the graduates of secondary schools, about to enter the universities, will no longer be necessary. Of the annual number of graduates from the secondary schools (about 44,000 at present) usually about 25,000 enter the universities. The new regulation reduces this number by 40 per cent. If the decision had been reached on the basis of present actual needs, it would have been necessary to close the universities to new entrants, for the time being. There is at present a total of 120,000 German students in attendance at the universities, so that only four years, at the most, will be required, according to the new schedule to reduce the total to 60,000, which will correspond to the status of the prewar years. It remains to be seen whether this new regulation will deal a death blow to the three new universities that were established since the war in order to make a university education more generally accessible (Cologne, Hamburg and Frankfurt-on-Main). Another influence of some importance is the fact that the attendance of foreign students appears to be diminishing rather than increasing. At the large universities—more particularly Berlin—where the heavy afflux of students, for many years past, has led to an overcrowded condition, the new regulation will greatly improve the situation. Of the smaller universities, it is not impossible that a few will have to struggle for their continued existence.

In the future, the privilege of attending a university will be based on four criteria: attainment of the necessary intellectual and physical maturity to satisfy the demands of intensive study, quality of character, and "national reliability." The recognition or the denial of the proper maturity for university study will be incorporated in a special certificate issued on request and may not be noted on the pupil's regular graduation diploma, for it is not deemed desirable that two distinct categories of secondary school graduates be created. While it is impossible at present to express a final opinion on these measures with respect to their ultimate effects on the quality of the future scientific accomplishments of the new order of students, it is certain that the new regime will check the growth of an evil that has been becoming prevalent in Germany, namely the exaction of exaggerated qualifications as a result of which a secondary school, or even university, education has come to be demanded of candidates for positions that require no such training.

Concerning the physicians, the statement was made, as one justification of the law, that by 1935-1936, the number of new graduate physicians will be from two to three times the number actually needed, when further restrictions will be necessary.

The repercussive effects of the new principles and the recently established societies of university instructors (*THE JOURNAL*,

Dec 1, 1933, p 1980) gave rise to an address delivered by Ministerialrat Dr Haupt, before the Dozentenschaft of the University of Berlin, on the "Relation of National Socialism to Science." He emphasized that national socialism is not demanding anything revolutionary of science. It is recognized that research cannot be pinned down to narrow rules. It is realized also that not every one who joins a new organization becomes thereby a new man. One of the main purposes of organization today is to develop, in the minds of all citizens, a deep sense of solidarity. It is admitted, however, that these types of intellectual work presuppose an opportunity for selection. It is not expected of research workers that they shall throw themselves with enthusiasm into the work of any society in order thus to give external evidence of their full allegiance to the cause of the German people. But of the large group that heretofore held themselves aloof as outsiders it must be demanded that, during this transition period at least, they give some visible evidence of their sense of oneness with the German people, as revealed, for example, by participation in national parades and public gatherings.

The position of non-Aryan students has been further intensified. At the beginning of the winter semester, a notice was posted at the University of Berlin concerning the admission of non Aryans, which was to the effect that all those who have not been excluded will find in their record book a special entry concerning their admission to further study. The non Aryan students receive a yellow identification card, and the Aryans a gray card. Furthermore, the president (rector) of the University of Berlin, Prof Eugen Fischer, who holds a chair in the science of heredity, has announced that, according to a bulletin received from the Prussian ministry for science and education, non Aryan medical students cannot count on receiving a license to practice medicine. Since, according to the present regulations, the medical and dental doctor's diploma is delivered only to foreigners without reference to whether or not they are granted a license to practice medicine (dentistry) in Germany, the only course left to non-Aryan German citizens who desire the doctor's diploma before securing a license to practice medicine (dentistry) is to renounce their German citizenship and to request liberation from allegiance to Germany. The pursuit of a medical practice in Germany is of course inadmissible for all such students.

Increase in Miscarriages

Since 1902 the number of miscarriages reported by the German maternity hospitals, in comparison with the normal births and premature births, has increased. The adjacent tabulation gives a survey of the conditions in the German maternity during the period from 1902 to 1930 inclusive.

Conditions in German Maternities

Years	Normal and Premature Births	Miscarriages	Percentage of Miscarriage with Relation to Normal and Premature Birth
1902-1904	104,757	9,347	9.0
1911-1913	190,471	8,466	4.4
1917-1919	164,707	19,222	11.6
1920	83,024	8,021	9.7
1922	70,413	8,681	12.3
1924	70,964	10,679	15.1
1926	102,227	11,319	11.0
1928	110,761	12,344	11.1
1929	113,632	15,229	13.4
1928	123,440	18,924	15.3
1929	130,712	21,093	15.9
1930	130,368	21,397	16.4

The criminal abortions are performed in the main, outside of hospitals and do not affect these statistics. An example is furnished by Lubeck where the number of miscarriages was determined by questioning all the midwives, physicians and hospitals. This inquiry revealed that in 1924 there were 168

miscarriages for each 100 confinements, whereas during the period 1926-1931 the proportion of miscarriages ranged around one third of the confinements (1930, 31.8, 1931, 33.7)

The number of persons accused of abortion and receiving a court sentence was 7,809 in 1925 (the maximum number), while in 1930, the last year for which general statistics have been published, the number of persons accused of abortion dropped to 4,111. These figures include the pregnant women and their helpers. Of the 4,111 accused, 3,648 were found guilty and given a sentence, in which number 1,105 men and 2,543 women were involved. The proportion of men was 30 per cent (in 1927, 27 per cent)

A Record for Human Fertility

A short time ago in Vienna a woman aged 48 gave birth to her twenty-ninth living child. The birth, which took place in a hospital, took a normal course and was completed within two hours and a half. Of the twenty-nine children, sixteen are still living—twelve sons and four daughters. Seven sons and six daughters have died. There have been no twin births. In three different years two children were born in one year (January and December). If the statements of the woman are reliable, all her children were normal, and the thirteen children who died were lost only through children's diseases. She gave birth to her first child when she was 19 years old, and she has always had normal pregnancies and normal childbirths and puerperium. An attempt is being made to examine the living children (who are widely scattered) with reference to their fertility and the nature of the offspring, in order to study certain problems of hereditary transmission.

Inherited Predisposition to Tuberculosis

At one of the recent sessions of the Gesellschaft der Aerzte in Vienna, Dr S. Peller and Dr M. Bettelheim reported the results of their examinations of 31,500 juveniles aged 14 to 16. Of this number 22 per cent were orphans, and 6 per cent had lost either father or mother as a result of tuberculosis. The investigators desired to establish whether the offspring showed a special predisposition for tuberculosis. Children of persons who had died from tuberculosis presented three times as frequently signs of tuberculous diseases, as orphans from non-tuberculous families, and four times as frequently specific symptoms of the respiratory organs. This hypermorbidity in juveniles born of tuberculous parents is revealed more commonly by the milder forms of the disease (involvement of the hilar glands), the graver types (apicitis, tertiary phthisis, pleuritic processes) being comparatively rare. This fact would indicate that the cause of the differences in the frequency of the infection does not lie in the predisposition to tuberculosis but is due rather to the factor of increased contamination. In general only slight differences exist between the average height, weight and the height weight ratio of juveniles from tuberculous families and the values in other juvenile orphans and nonorphans. An inherited physical inferiority in those whose parents were tuberculous could not be demonstrated. In the children who had become orphans by reason of tuberculosis, slight differences existed in weight and height (as compared with the average population) but were ascribable rather to the differences in the environment. Motherless half-orphans were usually weaker and smaller than half-orphans bereft of the father, which fact is due to the effects of unequal developmental conditions. It depends somewhat, too, whether the children become orphans before they reach school age or later and whether there are many children—in other words, the social factor dominates. In the case of 1,600 girls examined in recent months in addition to the measurements mentioned the thoracic

girth, in maximal inspiration and expiration, was measured, and the chest expansion was determined. These examinations likewise failed to prove that in the children infected by parents the "asthenic" habitus was more frequent than in the general population. It was found also that, in recent years, the children of tuberculous parents, as well as the other juveniles, have, as a rule, become taller and heavier. It is apparent, therefore, that the influences which, in spite of unfavorable economic conditions, are bringing about a steady improvement in the development of youth in general, are operative in the same manner in tuberculous and nontuberculous offspring. This proves that not eugenic factors but the nature of the entire social fabric determines the course of the development. In combating tuberculosis as a racial disease, these factors should receive primary consideration.

Right of Physicians to Privileged Communication in Public Sanatoriums

The ministry of public health recently informed the public and private hospitals and sanatoriums that the physician's right (and duty) of privileged communication must be strictly preserved, except when public interests (which are specifically enumerated) make it necessary that case reports or other facts affecting the treatment of hospital patients be communicated to third parties. As a rule, copies of case reports should not be given out. Only the courts and the accident insurance departments of public corporations (for example, state-controlled railways) and of public pension institutes have the right to demand such copies. The courts may demand also the privilege of inspecting the original case reports. Toward private sick-benefit societies or insurance companies, the duty of guarding privileged medical communications, on the part of physicians, is absolute. Case reports should not be given out to unauthorized persons, even with the consent of the patient. Only when the question of the need of hospital treatment and the probable duration of such treatment is to be decided can information be given to private corporations. Concerning the course of a disease, or possibly concerning a necropsy report, information may be given to a confidential physician who can identify himself, provided the settlement of the affair in question is impossible without such information. The supplying of information personally to physicians serving in sanatoriums is prohibited. Any information to be supplied must take place through the management. These provisions have of course nothing to do with information given to the near relatives and friends of patients.

Use of Methylthionine Chloride, with Dextrose, in Illuminating Gas Poisoning

During the past eight months, experiments have been carried on in Vienna, in the Childs Hospital, erected with the aid of an American gift, in the resuscitation by chemical means of persons overcome by illuminating gas. Before the Gesellschaft der Aerzte, Dr F. Deutsch gave recently an account of these experiments. On the basis of extensive animal experiments, and taking account of observations of American physicians who recommended methylthionine chloride in cyanide poisoning, Dr Deutsch injected intravenously a mixture of dextrose and methylthionine chloride in cases of poisoning from illuminating gas and achieved excellent results. In Vienna, illuminating gas is used frequently as a means of committing suicide. In accordance with an understanding with the hospital authorities, the emergency ambulance corps has been transporting to the Childs Hospital all grave cases of this nature, where Dr Deutsch in person has been applying his new method. The exceedingly rapid return of respiration and color in persons receiving such an injection has been remarkable. The preparation effects a rapid detoxication of the blood, with the result that the preparation is changed into a colorless compound

With this method it has been found possible to resuscitate persons who have lain for seven hours in a gas-filled room but who were not yet dead. The preparation is to form part of the regular equipment of the ambulance corps, in order that it may render immediate aid in accidents or attempted suicide. The physicians of the ambulance corps report that with this preparation the lives of persons can be saved who otherwise would succumb to the intoxication. Further experiments will be undertaken to discover whether persons overcome by other gases besides illuminating gas can be resuscitated in a similar manner.

Operations for Colloid Goiter

Prof. Dr. Eiselsberg spoke recently at the medical "seminar" of the Vienna Faculty of Medicine on operations for colloid goiter. He stated that colloid goiter must be operated on if it is growing rapidly or if it is blocking respiration—sometimes also for cosmetic reasons. The indications may be elicited by having the patient speak rapidly, walk rapidly or climb stairs. The resulting compression of the trachea may be made objectively visible by means of laryngoscopy or a roentgen examination. Before an operation is undertaken an examination must be made to determine whether the tracheal wall is soft and if so, the exact degree of softness. If the tracheal wall is very soft, a portion of the thyroid may be left at the operation as a support at this point, in order to prevent a collapse of the tracheal wall. In former times tracheotomy often had to be performed, frequently followed by plastic operations. It is better to leave a remnant of the gland than to apply dilatation sutures after the Kocher method. Softening of the tracheal wall may persist for some time after a successful operation, hence, a patient just operated on should be cautious about turning his head suddenly or exerting himself in any way that might cause dyspnea. Professor Eiselsberg operates on colloid goiters, in juveniles under 15 years of age, only in urgent cases. In such patients he prefers a treatment with weak doses of iodine taken internally or iodized ointment applied externally.

In Vienna, the incidence of colloid goiters in school children is surprisingly high. About 40 per cent of the girls from 6 to 14 years of age present such goiters. For this reason a number of years ago, the use of iodized salt (5 mg. to 1 Kg.) was made almost obligatory. But now it appears that the population is sufficiently "iodized" for, if one considers only the adults, there appears to be a distinct decrease in the number of goiter patients, as compared with five years ago.

Chemical Diagnosis of Malignant Tumors

At a session of the Vienna Biologic Society, Dr. R. Links, chemist of the Radiotherapeutic Institute of the city of Vienna, reported on his research on the case material of the institute. He has found that the potassium, calcium and magnesium content of the blood serum varies greatly, dependent on the time when the collected serum is examined, that is whether or not it has stood a long time. Dr. Links has constructed an apparatus that allows every cubic centimeter of serum issuing from the coagulated blood to be examined at once. Further research has revealed that the relation of the magnesium content to the potassium content of the blood varies according as the patient is or is not affected with cancer. If one selects 100 to represent the normal relationship, it is significant that, in the presence of tumors, the numerical relationship was without exception, expressed by a figure above 100, whereas, in all other conditions the relationship was denoted by a figure under 100. Numerous control examinations of patients with tuberculosis, infectious diseases and surgical diseases and of persons in good health, were made, and again and again it was found that this chemicomathematical method gave unequivocal results. In 99 patients with verified neoplasms the tests were positive and in 110 with other diseases they were always negative.

Marriages

JOHN RANDOLPH PERDUE, Rocky Mount, Va., to Miss Jean Barksdale Jones of Petersburg, Dec. 2, 1933.

WILLIAM HENRY GOFCKERMAN, Los Angeles, to Miss Betty Moore of Rochester, Minn., Oct. 18, 1933.

WILLIAM AMBROSIO MCGUFF, to Miss Lois Imogene Lacy, both of Richmond, Va., Dec. 9, 1933.

HARRY W. SHUMAN, Rock Island, Ill., to Miss Ruth Lewis of Chisholm, Minn., January 2.

JASPER NEWTON WAKEMAN to Miss Anne Peightel, both of Springfield, Mo., February 10.

DAVID R. ROSENDALE to Miss Lucille MacArthur, both of Utica, N. Y., Dec. 21, 1933.

EDWARD S. EMERY, Brookline, Mass., to Miss Mary Bradley of Milton, in January.

ROBERT B. BRAY to Miss Eleanor Burnett, both of Fargo, N. D., recently.

DONALD KEYS to Miss Elizabeth Laughry, both of Chicago, February 3.

Deaths

Louis Simon Aronson of New York, Columbia University College of Physicians and Surgeons, New York, 1904, member of the Association for Research in Nervous and Mental Diseases, on the staffs of the Mount Sinai Hospital, Bronx Hospital and Dispensary, Morrisania City Hospital, Vanderbilt Clinic and the New York Infirmary for Women and Children, aged 52, died, February 1, of heart disease.

John S. Van Duyn, Syracuse, N. Y., Kentucky School of Medicine, Louisville, 1865, professor emeritus of surgery, Syracuse University College of Medicine, veteran of the Civil Spanish-American and World wars, formerly on the staff of the Hospital of the Good Shepherd, aged 90, died January 15, of arteriosclerosis and hypostatic pneumonia.

Virgil Martha Gilchrist Wheeler, Urbana, Ill., University of Illinois College of Medicine, Chicago, 1917, served with the American Red Cross in France during the World War, medical adviser to women, University Health Station, and associate in hygiene, University of Illinois, aged 45, died, January 3, at her home in Monticello.

Bart Newton White of Murfreesboro, Tenn., University of Tennessee Medical Department, Nashville, 1909, formerly a dentist, past president and secretary of the Rutherford County Medical Society, served during the World War, aged 54, on the staff of the Rutherford Hospital, where he died, Dec. 20, 1933, of meningitis.

Leonard Hugh Douglass, London, Ont., Canada, Western University Faculty of Medicine, London, 1905, served in the Canadian Army Medical Corps during the World War for five years, alderman of London and for several years chairman of the board of health, died Oct. 11, 1933, following an operation on the jaw.

Richard Leo Sullivan, Baldwinsville, N. Y., Syracuse University College of Medicine, 1900, member of the Medical Society of the State of New York, past president of the Onondaga County Medical Society, for thirteen years health officer of Baldwinsville, aged 58, died suddenly, January 17, of heart disease.

Luther Swiggett Conwell, Camden, Del., Jefferson Medical College of Philadelphia, 1884, member of the Medical Society of Delaware, formerly member of the state legislature, at one time secretary, executive officer and registrar of vital statistics, state board of health, aged 74, was found dead, February 5.

Albert Benjamin Tonkin, Riverton, Wyo., Colorado School of Medicine, Boulder, 1904, member of the Wyoming State Medical Society, past president of the state board of health, veteran of the Spanish-American and World wars, aged 54, died January 18, in a hospital at Denver, of typhoid.

Huntington Richards, New York, College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1877, member of the American Otological Society, aged 83, died February 4, in the Phillips House, Massachusetts General Hospital, of bronchopneumonia.

Miles Egbert Varney, Saratoga Springs, N Y, University of Vermont College of Medicine, Burlington, 1889, member of the Medical Society of the State of New York, formerly county coroner, on the staff of the Saratoga Hospital, aged 71, died suddenly, January 23, of heart disease

Robert Henry Wolcott, Lincoln, Neb., University of Michigan Medical School, Ann Arbor, 1893, formerly junior dean and professor and head of the department of zoology, University of Nebraska College of Medicine, aged 65, died, January 23, of carcinoma of the liver

John Joseph Aloysius O'Reilly, Brooklyn, Long Island College Hospital, Brooklyn, 1901, member of the Medical Society of the State of New York, also a lawyer, aged 62, died, January 29, in the Long Island College Hospital, following an operation for appendicitis

E Mitchell Summerell, China Grove, N C, University of Pennsylvania School of Medicine, Philadelphia, 1883, member of the Medical Society of the State of North Carolina, aged 76, died, January 29, in Long's Sanatorium, Statesville, of heart disease

William Edward Errett, New Stanton, Pa., Western Pennsylvania Medical College, Pittsburgh, 1900, member of the Medical Society of the State of Pennsylvania, aged 60, died, in January, at the Westmoreland Hospital, Greensburg, of pneumonia

Homer Berkley Walker, Cumberland, Md., University of Vermont College of Medicine, Burlington, 1919, member of the Medical and Surgical Faculty of Maryland, on the staff of the Allegany Hospital, aged 43, died, Dec. 26, 1933, of pneumonia

Albert Rufus Sheldon * Highland Park, Ill., Hahnemann Medical College and Hospital, Chicago, 1902, member of the Radiological Society of North America, on the staff of the Highland Park Hospital, aged 56, died, February 6, of heart disease

William B Floyd, Rome, Ga., Atlanta Medical College, 1891, member of the Medical Association of Georgia, past president of the Floyd County Medical Society, on the staff of the McCall Hospital, aged 65, died, January 18, of heart disease

Rushton Clark Molloy, Columbus, Miss., College of Physicians and Surgeons, Baltimore, 1892, member of the Mississippi State Medical Association, on the staff of the Columbus Hospital, aged 64, died, January 7, of pernicious anemia

Roy Angelo Sadler * Boston, Harvard University Medical School, Boston, 1907, served during the World War formerly on the staffs of the Massachusetts General and Children's hospitals, aged 51, died, January 18, of coronary disease

Benjamin Franklin Young, Knoxville, Tenn., University of Tennessee Medical Department, Nashville, 1885, member of the Tennessee State Medical Association, aged 82, died, Dec 24, 1933, in the Fort Sanders Hospital, of senility

Martin Collins Woodruff, St. Louis, Beaumont Hospital Medical College, St. Louis, 1891, served during the World War, formerly member of the city board of health, aged 67, hanged himself, January 12, at the City Sanitarium

Frank Barton Schurtz, Spring Valley, Ill., University of Michigan Medical School, Ann Arbor, 1885, for many years president of the board of health of Spring Valley, aged 68, died, January 24, of cerebral hemorrhage

Cecil Ernest Wasgatt, Camden, Maine Medical School of Maine, Portland 1882, member of the Maine Medical Association, aged 80, died, January 9, of carcinoma of the prostate with metastasis to the cervical spine

Cyrus Bowers Eby * Spring Valley, Minn. University of Minnesota Medical School, Minneapolis, 1893, past president of the Fillmore County Medical Society, aged 61, died suddenly, January 20, of heart disease

Carl Robert O'Brien * Bangor, Maine, Tufts College Medical School, Boston, 1907, member of the Massachusetts Medical Society, served during the World War, aged 49, died January 9, of heart disease

Hallick Hart Look * Sacramento, Calif., College of Physicians and Surgeons, Medical Department of Columbia College, New York 1887, aged 71, died, Dec. 26, 1933, in the Sutter Hospital of arteriosclerosis

Albert LeRoy Crittenden * Shellman, Ga., Atlanta College of Physicians and Surgeons, 1902, past president of the Randolph County Medical Society, aged 54, was shot and killed January 25

Charles Edward Clayton, Birmingham, Ky., College of Physicians and Surgeons, Baltimore, 1884, member of the Kentucky State Medical Association, aged 74, died, January 21, of pneumonia

Samuel Marshall Utley, Nashville, Tenn., Meharry Medical College, Nashville, 1912, formerly professor of nervous and mental diseases at his alma mater, aged 65, died, January 25 of heart disease

Euclid D Covington, Murray, Ky., Hospital College of Medicine, Louisville, 1903, member of the Kentucky State Medical Association, aged 50, died suddenly, January 14, of heart disease

Robert C Dunkel, Cokedale, Colo., Denver and Gross College of Medicine, 1904, aged 53, died January 19, in the Mount San Rafael Hospital, Trinidad, of lobar pneumonia and myocarditis

Hugh F Wagley, Mineral Wells, Texas, Louisville (Ky.) Medical College, 1891, member of the State Medical Association of Texas, aged 68, died, Dec 12, 1933, of cerebral hemorrhage

Adam Glandorf Bormann, Toledo, Ohio, Medical College of Ohio, Cincinnati, 1881, aged 70, died, February 1, in St Vincent's Hospital, of burns received when a cigaret ignited a curtain

John Archibald McLean, Glace Bay, N S, Canada, Dalhousie University Faculty of Medicine, Halifax, 1924, aged 37, died recently, in the Victoria General Hospital, Halifax

Leroy S Wallace, Bunker Hill, Ind., Starling Medical College, Columbus, 1875, member of the Indiana State Medical Association, aged 79, died, January 12, of heart disease

James D Barr, Upper Sandusky, Ohio, University of Pennsylvania School of Medicine, Philadelphia, 1879, formerly a druggist, aged 86, died, January 29, of heart disease

Clark Ogden Decker * Crandon, Wis., Milwaukee Medical College, 1901, served during the World War formerly mayor, aged 62, died, January 20, of angina pectoris

John H Harkness, Belleville, Ark., Arkansas Industrial University Medical Department, Little Rock, 1881, aged 85, died, Dec 21, 1933, of carcinoma of the stomach

Charles Christian Rothfuchs, Boston, Harvard University Medical School, Boston, 1896, aged 60, died, January 24, of angina pectoris and coronary occlusion

Archibald Crosse Hunter, Goderich, Ont., Canada, Trinity Medical College, Toronto 1891, medical officer of health and coroner, aged 64, died, Dec 23, 1933

Clifton E Whitney, Little Rock, Ark. (licensed, Arkansas 1903), member of the Homeopathic State Medical Board, aged 67, died, January 16, of heart disease

Henry R Noark * Houston, Texas, University of Louisville (Ky.) School of Medicine, 1888, aged 69, died, Dec 7, 1933, of myocarditis and hypertension

Omer Joseph Ohrel, St. Louis, St. Louis University School of Medicine, 1930, aged 27, died, January 3, in the Christian Hospital, of septicemia

Samuel Tevis, Alameda, Calif., Jefferson Medical College of Philadelphia, 1888, also a lawyer, aged 74, died, Dec 11, 1933, of uremia and pyonephrosis

Levi St John Hely, Richmond, Calif., University of Michigan Medical School, Ann Arbor, 1899, aged 64, died, Dec 19, 1933, of angina pectoris

Lyman Trumbull Waggoner, Los Angeles, Missouri Medical College, St. Louis, 1889, aged 73, died, January 13, of a self inflicted bullet wound

Otto Leonard Wolter * St. Louis, Washington University School of Medicine, St. Louis, 1904, aged 58, died, January 22, of heart disease

Oliver Marion Chapman, Erie, Pa., University Medical College of Kansas City (Mo.), 1896, aged 70, died, January 26, of angina pectoris

John Urquhart, Oakville, Ont., Canada, Trinity Medical College, Toronto 1882, formerly mayor of Oakville, aged 89, died Dec 17, 1933

Charles L McKinnon * McKees Rocks, Pa., Western Pennsylvania Medical College, Pittsburgh, 1899, aged 63, died, Dec 31, 1933

Russel Duncan Brown, Flint, Mich., Detroit College of Medicine and Surgery, 1917, aged 39, died, January 30, of pneumonia

Perry Ernest Doolittle, Toronto, Ont., Canada, Faculty of Medicine of Trinity College, 1885, aged 72, died, in January

USE OF PROCAINE IN PAINFUL ARTICULAR CONDITIONS

To the Editor—In reply to Dr Ralph R Fitch's communication (*THE JOURNAL*, January 13, p 148), I would say that he seemed a bit hasty and unfair in his condemnation of the Paris correspondent's report of the use of procaine in certain painful articular conditions (*THE JOURNAL*, Nov 4, 1933, p 1492). I can understand his objection to permitting patients with severe sprains and luxations to use the part immediately, but the correspondent apparently referred to mild sprains and luxations in which the patient is grateful for relief locally. It appears to me a superior method of pain relief to the use of narcotics in cases in which the latter would be indicated.

As to the use of this method in selected cases of long standing painful monoarthritic conditions, I have two grateful patients on whom this mode of treatment was tried. I am not referring to cases of polyarthritic conditions in which the cause is known but rather to those cases of arthritis and peri-arthritis of several months' duration probably in most instances due to a known or suspected focus of infection. At any rate, when all other methods fail to produce relief of pain the injection method can do no harm if proper aseptic technic is observed.

Mrs A D, aged 35, had for several months been suffering with a painful right knee. Weight bearing was almost impossible. The popliteal space felt "knotted." The pain seemed to radiate down the anterolateral aspect of the leg. She was unable to do housework and had been using a crutch to get about the house. Physical examination revealed a moderate degree of obesity and suspicious looking tonsils. About a year before a peritonsillar abscess had been incised and drained. I advised a reduction diet and tonsillectomy, the latter of which she would not have done at present. I gave her such medications as salicylates, iodides and neocinchophen. She showed absolutely no improvement after a few weeks of such treatment. Finally, and with some tenuity, I injected 10 cc of a 1 per cent solution of procaine hydrochloride into the insertion of the tendons and ligaments of the knee. While the patient experienced no immediate relief within two or three weeks she was limping about the house unaided and in six or seven weeks she was clinically as well as ever. Three months has elapsed with no recurrence.

I am of course not advocating the indiscriminate use of this mode of treatment but am only relating my own experience and defending a suggestion which would warrant further clinical trial.

J C WEISMAN, M D, Elizabeth N J

EXAMINATION FOR AMEBIASIS

To the Editor—In the recent articles and discussions on amebiasis appearing in *THE JOURNAL* no mention is made of a valuable aid in the detection of the organisms. In 1929 at the Boston City Hospital, under the care of Dr George C Shattuck, chief of the tropical service there were sixteen patients with active amebiasis practically all being residents of the city. The diagnosis was quickly and easily made by examining the bloody mucus or liquid stool, with the microscope in a hot box, which keeps it indefinitely at body temperature. The amebas at body temperature are actively motile, and if blood is present the red cells are easily seen in the cytoplasm. As soon as the temperature falls, activity ceases and then their detection is extremely difficult. It is not necessary for the specimen to be collected in a warm container or that it be kept warm after passage or that it be examined immediately. However, drying out of the specimen or contamination with urine should be avoided.

WILMOT C TOWNSEND, M D, Hartford Conn

CASTOR OIL AND QUININE FOR INDUCTION OF LABOR

To the Editor—What is the present opinion and practice regarding the use of (a) castor oil and (b) quinine with or without solution of pituitary, for pregnant women who go over time and are anxious to deliver? Please omit name, town and state. M D, California.

ANSWER—Castor oil and quinine are still used almost universally as medicinal means of inducing labor, but the results are not uniform. At or beyond term, these drugs are successful in perhaps 25 per cent of the cases. Because of the uncertainty involved, Watson suggested the use of solution of pituitary as a supplementary method. His technic is as follows:

At 6 p m, castor oil, 30 cc
At 7 p m, quinine, 0.65 Gm
At 8 p m, large soap suds enema
At 9 p m, quinine, 0.65 Gm
At midnight, quinine, 0.65 Gm

If pains have not occurred by 9 o'clock of the following morning, 0.5 cc of solution of pituitary is given hypodermically and repeated every half hour until labor sets in or until six doses have been administered. This method is effective in most cases, but the large doses of solution of pituitary and the large amount of quinine used are dangerous. Solution of pituitary in the doses given often results in tetanic contractions of the uterus and may possibly lead to rupture of the uterus. Quinine has occasionally caused the death of babies in utero, hence most physicians who give quinine prescribe only from 0.65 to 1 Gm altogether. However, even this dose is too high to obtain the best results, because it has been shown recently that small doses are much more effective for stimulating uterine contractions than are large doses. Likewise at present small amounts of solution of pituitary are administered usually 0.1 or 0.2 cc at a time. Because it is difficult to inject exactly 0.1 or 0.2 cc with the ordinary hypodermic syringe, it is best to use a specially marked one like a tuberculin syringe. Even with such small doses, tetanic contraction of the uterus may result, hence care must be exercised regardless of how small the dose is.

A number of years ago, Hofbauer demonstrated that solution of pituitary may be applied to the nasal mucous membrane and produce an oxytocic effect on the uterus. His method consists of soaking a pledget of gauze with 1 cc of solution of pituitary and inserting the pledget beneath the inferior turbinate bone. After a few minutes, uterine contractions are usually observed. This method is safer than the hypodermic administration, because the rate of absorption of the solution of pituitary is slow and because the solution of pituitary may be removed as soon as unusually violent contractions of the uterus are noted. When this method is used, castor oil and quinine should be administered first and the pledget should be inserted into the nose about three hours after the last dose of quinine is given. If labor pains do not set in after thirty minutes, the pledget should be removed and another one inserted on the opposite side of the nose. A third and a fourth pledget may have to be used before the desired results are obtained. The intranasal application with castor oil and quinine is successful in about 75 per cent of the cases at term. However, even the intranasal use of solution of pituitary may result in undesirable contractions, hence here again the cases must be properly selected and carefully watched.

PHRENICECTOMY

To the Editor—Will you please describe the anatomic landmarks that will enable one to locate the phrenic nerve, the technic of the operation for section of this and your opinion as to its relative value in relation to artificial pneumothorax. Please give reference as to articles or books in which this is described.

F C McCLANAHAN, M D, Assiut, Egypt

ANSWER—The phrenic nerve passes over the anterior scale of the subclavian artery, obliquely from behind forward, a short distance above the clavicle. A convenient incision is one-half inch above the clavicle and parallel with it about 5 cm long. The middle of the incision lies over the external border of the sternocleidomastoid muscle. The wound is spread somewhat to mobilize the outer edge of the sternocleidomastoid muscle, which is then retracted inward.

exposing the scalenus anticus with some gland-bearing fat overlying it. This must be dissected through and retracted. Normally the nerve is then seen lying in front of the muscle. It may be either crushed or extracted (excised). Crushing it results in complete paralysis of the diaphragm on the operated side in perhaps 75 per cent of the cases. In the other 25 per cent some tributaries which enter the main trunk below the level of the clavicle maintain a partial innervation. For this reason, if it is desirable to obtain complete paralysis, the nerve should be excised. This is done by separating it from the muscle, clamping it with a hemostat, cutting it and then winding the distal part on to the hemostat very slowly. In most cases this will bring away at least 10 to 25 cm of the nerve and all tributaries.

A phrenic nerve resection produces a 15 to 30 per cent reduction in the volume of the pleural cavity on the operated side, and a corresponding degree of rest of the lung because of the immobilization. This amount of collapse and rest of the lung may be sufficient to bring about an arrest of a tuberculous lesion, but usually, the more complete collapse of the lung secured by artificial pneumothorax or by thoracoplasty may be necessary. In suitable cases phrenic nerve operation may be done first and pneumothorax collapse performed later, if symptoms persist.

A good description of the operation may be found in Howard Lilenthal's "Text-Book of Thoracic Surgery" and John Alexander's monograph on the "Surgery of Pulmonary Tuberculosis."

NARCOTIC ADDICTION IN A NURSE

To the Editor—I have a patient a trained nurse whose husband accuses her of being a morphine addict. She has had an appendectomy, the gallbladder was removed on account of stones, then the right kidney was removed and the colic continued. About a year ago a small stone was removed from the common duct. I had her in a hospital for four days. She showed no signs of morphinism; she took nothing but a night gown and a few cigarets into the room with her. These were inspected before she was allowed to have them. Please advise me what measures to follow to disprove the charge. M D Wisconsin

ANSWER—An addict nurse can outwit almost any physician who has not had an extensive experience treating narcotic patients.

Wise addicts who are using morphine hypodermically know that from one and one-half to two times their daily amount taken by mouth will keep them in balance and prevent a "yen" or abstinence symptoms.

The patient referred to could have had morphine concealed in her hair, ears, mouth, vagina or rectum (in a rubber finger cot in the three latter locations). Linen or handkerchiefs could have been soaked in a strong morphine solution and sucked or redissolved as needed. She could have arranged or made contact with people in or out of the hospital to smuggle her morphine in the food, medicine, clothing, books or papers. After a complete examination she should have been stripped to the skin and a night gown and other clothing supplied in which she could not conceal morphine. She should then have been put under constant surveillance by trustworthy, experienced attendants. It might also be advisable to give her an opportunity to cheat through a relief attendant.

If these instructions cannot be carried out, she should be placed under the care of a physician experienced in narcotic addiction.

CEREBROSPINAL SYPHILIS

To the Editor—Please give treatment for cerebrospinal syphilis and proper technique for making silver arsphenamine solution.

JOHN W. MARTIN, M.D. Roanoke Rapids, N.C.

ANSWER—Cerebrospinal syphilis is a term that includes a good many clinical syndromes. In some cases the disorder is due in large part to vascular disease; in other cases to meningeal inflammation. The treatment must, of necessity, vary considerably in different patients with different pathologic types. In a general way it may be said that in some of the milder cases a combination of arsphenamine and bismuth compounds will be quite effective. In other instances tryparsamide, assisted by these other drugs, will be the method of election and in a limited number of cases febrile treatment would probably be best. In the cases of pure vascular disorder the iodides will be the main drugs with possibly a small amount of bismuth or very small doses of arsphenamine.

Silver arsphenamine is prepared by dissolving the drug in sterile distilled water. Occasionally a little scum occurs; hence it is well to filter the solution through sterile gauze.

POSTMORTEM DIGESTION OF STOMACH

To the Editor—Will you kindly give me what information you have concerning the postmortem digestion of the stomach? Under what conditions does this occur and how soon after death might digestion take place to such a degree as to cause a large perforation of this organ together with perforation of the diaphragm?

GEORGE F. STONEY, M.D. Erie, Pa.

ANSWER—Self digestion of the stomach may occur in varying degrees under a great variety of conditions. The process may begin soon after death, especially in the parts that are in contact with the digestive fluid, notably the posterior wall of the fundus and at the esophageal junction. The state of secretory activity at the time of death naturally must be of much importance. Self digestion is frequent in small children, also, it is said, in persons who are killed by lightning, and following death from cerebral disease. Warm weather favors the process. The digestion may involve the entire thickness of the wall of the stomach and extend to neighboring organs, such as the spleen, the liver, the diaphragm, the lungs and the pericardium. In rare instances, cavities may be produced in the lungs. Just how soon after death digestion may extend through the wall of the stomach and diaphragm cannot be stated definitely, because of the great variability of the factors concerned.

TAYLOR BLAIR METHOD FOR BLOOD UREA

To the Editor—In a note on Karr's method for blood urea in *THE JOURNAL* Nov. 25, 1933 you mention the Taylor Blair modification as superior. I am using Karr's method and I should be interested in learning the details of the Taylor Blair method of which I have not previously heard. It is not given in Kolmer's approved methods, which is the latest book I have. Kindly omit name if published. M.D. Maine

ANSWER—In the Taylor-Blair method (*J. Lab. & Clin. Med.* 17:1256 [Sept.] 1932), crystalline urease is prepared from defatted jack bean meal by Sumner's method (*J. Biol. Chem.* 69:435 [Aug.] 1926, 70:97 [Sept.] 1926, 76:149 [Jan.] 1928). The crystals from 75 Gm of defatted jack bean meal are suspended in 5 cc of water and preserved with toluene containing 5 per cent of thymol. To 5 cc of whole oxalated blood is added 1 drop of the urease suspension plus 10 cc of water. It is incubated for fifteen minutes at 50°C. Next are added 25 cc of water, 5 cc of 10 per cent sodium tungstate, mixed, and then the usual 5 cc of two-thirds normal sulphuric acid. To 5 cc of the filtrate in a 25 cc graduate 15 cc of water and 25 cc of Nessler reagent are added and the mixture is diluted to 25 cc. It is nesslerized against a standard of 0.4 mg of nitrogen in a 100 cc volume. The results are slightly higher than urea by aeration methods. Recovery of added urea was from 99.4 to 101.1 per cent. The same filtrate can be used for protein nitrogen, Folin-Wu blood sugar, creatinine, and uric acid, according to Taylor and Blair.

SIGNIFICANCE OF MORNING DROP AFTER GONORRHEAL URETHRITIS

To the Editor—Please inform me through *Queries and Minor Notes* concerning the diagnosis and treatment of the so-called morning drop following acute anterior gonorrheal urethritis. Please omit name.

M.D., Louisiana

ANSWER—The persistence of a morning drop following an attack of gonorrheal urethritis may be due to the fact that the local treatment has been continued too long or that the drugs have been too strong. It is well known that in certain patients the urethra is sensitive to too long continued instrumentation and also to the long continued use of silver salts. Therefore, under these circumstances, if the urethral discharge no longer shows gonococci, local treatment may be discontinued or astringent injections used, such as a solution containing 0.065 Gm each of zinc sulphate, phenol (carbolic acid) and alum in 30 cc of water. The patient should inject this twice a day.

In the second place, a morning drop is often due to granulations in the anterior urethra or to strictures. These are best treated by the passage of large sounds. The sound should be allowed to remain in the urethra a minute or two and the urethra massaged over the sound and this may be followed with a mild anterior irrigation of warm potassium permanganate solution in the strength of 1:4,500.

In the third place, a morning drop may be due to the presence of infection in the prostate, or seminal vesicles, or both, the prostate and vesicles should be stripped and the fluid examined by the microscope for the presence of pus.

Finally, a morning drop may be due to the presence of infection in the glands of Littre and the crypts of Morgagni. These are best treated by destruction of the glands with the high frequency current.

DOSAGE OF VIOSTEROL IN RICKETS

To the Editor—Why is the average prophylactic and curative dose of cod liver oil 1,596 Steenbock units daily whereas the daily prophylactic dose of viosterol in oil 250 D is from 5,000 to 10,000 units and the curative dose from 10,000 to 20,000 units? Is viosterol in oil 250 D unit for unit, less effective than cod liver oil? A representative of a drug house has made such a claim. Please omit name.

M D, New York

ANSWER—There seems to be some confusion in regard to the number of units of cod liver oil and of viosterol required to prevent or to cure rickets. This is not surprising in view of the various types of units that exist and are used in advertising antirachitic agents. The average dose of cod liver oil is not 1,596 Steenbock units daily but about 200 units, and the corresponding dose of viosterol does not run into the thousands but is about 800 units, in other words, 10 drops a day of the preparation that contains about 80 units to the drop. It is true that, unit for unit, viosterol in oil 250 D is less effective than cod liver oil, this is of course, the reason for the larger dosage of the former. Whether this is due to a difference in nature of the vitamin D of the two substances has not yet been satisfactorily proved.

RICE FEVER

To the Editor—What is the modern equivalent of the term "rice fever"? This term was used by a Philadelphia author about 1810 in describing a fever common in China and supposed to be due to miasms in the rice fields.

MILOSH KASICH M D New York

ANSWER—We have found no dictionary, old or new giving the term "rice fever." It is presumably equivalent to malaria. Reports from Georgia prior to 1840 describe febrile disturbances in the rice country which are attributed to miasms following the flooding of the rice fields. The word "rice fever" is not specifically used in any publication we have seen. The original reference would have been of help. In the Georgia reports the fever is described as of summer and early fall incidences. The descriptions indicated that both malaria and yellow fever were included under the fevers attributed to miasms in the rice regions. As yellow fever does not appear to have occurred in China at the time indicated, presumably the term referred to malaria.

EFFECTS OF MOON ON LUNACY

To the Editor—Is there any evidence whatever based on medical statistical or other study of mental patients to support the belief that mental patients show periods of increased insanity or become more manic or are harder to control during certain phases of the moon while they show decreased signs of insanity and are more easily managed during certain other phases of the moon? Please omit name.

ANSWER—No

M D Virginia

PERSISTENT URTICARIA

To the Editor—I am deeply interested in the report of a case of urticaria of seventeen years standing by Emmett and Logan in THE JOURNAL Dec 16 1933. I have a daughter of about the same age who teaches school and is anything but neurotic. For several years say three she too had urticaria almost daily. I had her see physicians who I felt were better qualified to run the cause down. Tests diets nothing helped her so that she quit consulting these specialists and in desperation sought my advice. For several days I could think of nothing to do. Finally I asked her and learned that though a girl of fine physique and good health save for a headache rather frequently her menses though fairly regular were scanty. I put her on an ovarian preparation and as if by magic her hives and headache left her. Some three or four weeks after this she was unable to get this particular product from the usual source our local druggist and thinking it of no consequence if she went without it for a few days she omitted it. The third day the hives trooped back. Briefly then if she takes ovarian substance or extract she has no hives nor headache. Her improvement is nearing a year's trial.

W L JOHNSON, M D San Marino Calif

ACROPAESTHESIA

To the Editor—In Queries and Minor Notes in THE JOURNAL January 27 there is an inquiry regarding the treatment of the symptom complex known as acroparesthesia. In the August 1907 issue of the Philadelphia Medical Council I published an article under the heading Acroparesthesia (p 27) in which I stated that the only remedy which I had found invariably effective was potassium iodide. This condition is of frequent occurrence in this locality and while not dangerous is exceedingly annoying. Since writing the article referred to I have had an extensive experience and in the twenty four years my faith in this treatment has been confirmed. There is a chapter on page 333 of Observations of a General Practitioner (Gorham Press Boston 1932) which, I believe throws further light on the treatment and possible etiology of this obscure condition.

ADDITIONAL HOSPITALS APPROVED

The Council on Medical Education and Hospitals of the American Medical Association has given its approval to the following hospitals since the publication of the last previous list in THE JOURNAL, Oct 7, 1933.

Hospitals Approved for Intern Training

Little Company of Mary Hospital Evergreen Park Ill
St Anthony's Hospital Rockford Ill
St Luke Hospital Pittsfield Mass
State Infirmary Tewksbury Mass
Battle Creek Sanitarium Battle Creek, Mich
Menorah Hospital Kansas City Mo
Our Lady of Victory Hospital Lackawanna N Y
Yonkers General Hospital Yonkers N Y
Peoples Hospital Akron Ohio
Oklahoma City General Hospital Oklahoma City
Braddock General Hospital Braddock Pa
Holy Cross Hospital Salt Lake City
La Crosse Lutheran Hospital La Crosse Wis

Hospitals Approved for Residencies in Specialties

Children's Hospital, Birmingham Ala Pediatrics
Mount Zion Hospital San Francisco Medicine pathology and surgery
Fairmont Hospital of Alameda County San Leandro Calif Tuberculosis
Hartford Municipal Hospital Department of Communicable Diseases
Hartford Conn Communicable diseases
Norwich State Tuberculosis Sanatorium Norwich Conn Tuberculosis and thoracic surgery
Bell Memorial Hospital Kansas City Kan Medicine obstetrics gynecology pathology pediatrics and surgery
Church Home and Infirmary Baltimore Medicine and surgery
Maryland General Hospital Baltimore Medicine and surgery
Boston Lying in Hospital Boston Obstetrics
Battle Creek Sanitarium Battle Creek Mich Medicine psychiatry surgery and urology
Providence Hospital Detroit Medicine obstetrics and surgery
Michigan State Sanatorium for Tuberculosis Howell Mich Tuberculosis
Jackson County Sanatorium Jackson Mich Tuberculosis

Brooklyn Eye and Ear Hospital Brooklyn Ophthalmology and otolaryngology
Lincoln Hospital New York Pathology
New York Polyclinic Medical School and Hospital, New York Surgery and ophthalmology otolaryngology
Bloomington Hospital White Plains N Y Psychiatry
Dr W H Groves Latter Day Saints Hospital Salt Lake City Surgery

Hospitals Approved for Additional Residencies

New Haven Hospital New Haven Conn Ophthalmology, orthopedics otolaryngology, psychiatry tuberculosis and urology
University Hospital Augusta Ga Pediatrics
Children's Memorial Hospital Chicago Orthopedics (Fellowship Offered under auspices of Northwestern University Medical School)
Michael Reese Hospital Chicago Malignant diseases, ophthalmology and radiology

Massachusetts July Examination

Dr Stephen Rushmore, secretary, Massachusetts Board of Registration in Medicine, reports the written examination held in Boston, July 11-13, 1933. The examination included 46 questions. An average of 75 per cent was required to pass. One hundred and forty two candidates were examined, 70 of whom passed and 72 failed. The following schools were represented:

School	PASSED	Year Grad	Per Cent
Yale University School of Medicine	(1929)	77	
Georgetown University School of Medicine	(1933)	75, 78.9	
Emory University School of Medicine	(1926)	75.8	
Chicago Medical School	(1933)*	79.8	
Rush Medical College	(1927) 79.5	(1933)	80.1
School of Med of the Div of the Biological Sciences	(1933)	83.7	
Tulane University of Louisiana Medical Department	(1912)	75	
Johns Hopkins University School of Medicine	(1933)	81.3	
Boston University School of Medicine	(1930)	78.4

Maryland Homeopathic Report

Dr John A Evans, secretary, Homeopathic Board of Medical Examiners, reports the written examination held in Baltimore Dec 13-14, 1933. The examination covered 9 subjects and included 70 questions. An average of 70 per cent was required to pass. Three candidates were examined, all of whom passed. One physician was licensed by reciprocity. The following school was represented:

School	PASSED	Year Grad	Per Cent
Hahnemann Med Coll and Hosp of Philadelphia	(1933) 82 83 87		

School	LICENSED BY RECIPROCITY	Year Grad	Reciprocity with
Hahnemann Med Coll and Hosp of Philadelphia	(1907)	Wisconsin	

District of Columbia Reciprocity Report

Dr W C Fowler, secretary, Commission on Licensure, reports 6 candidates licensed by reciprocity from Sept 15 to Nov 23, 1933. The following schools were represented:

School	LICENSED BY RECIPROCITY	Year Grad	Reciprocity with
State University of Iowa College of Medicine	(1918)	Iowa	
College of Physicians and Surgeons	(1926)	Maryland

University of Virginia Department of Medicine	(1921) W Virginia		
Osteopaths *		Texas	

* Licensed to practice osteopathy and surgery

Book Notices

Diseases of the Chest and the Principles of Physical Diagnosis By George William Norris A.B. M.D. Chief of Medical Service, A. Pennsylvania Hospital and Henry R. M. Landis A.B. M.D. Sc.D. Professor of Clinical Medicine in the University of Pennsylvania. With a chapter on the Transmission of Sounds Through the Chest By Charles M. Montgomery M.D. and a chapter on the Electrocardiograph in Heart Disease By Edward B. Krumblhaar Ph.D. M.D. Professor of Pathology, University of Pennsylvania School of Medicine. Fifth edition. (Cloth) Price \$10. Pp. 997 with 478 illustrations. Philadelphia & London: W. B. Saunders Company, 1933.

This book, since its appearance in 1917 has merited wide use because it has been revised sufficiently often to keep abreast of the times. The present edition brings together not only all the well established facts concerning the principles of physical diagnosis, with special reference to diseases of the chest, but also most of the new material that is appropriate for such a book. Its authors not only are clinicians of renown but also have had long experience in teaching students of medicine. The book contains twelve chapters on the examination of the lungs, eight on the examination of the circulatory system, four on diseases of the bronchi, lungs, pleura and diaphragm and seven on diseases of the pericardium, heart and aorta. Each of the thirty-one chapters is carefully written and contains a vast store of information. Recent advances in medicine, such as those made on the vital capacity of the lungs, iodized oil in diagnosis, bronchoscopy, pneumoconiosis, massive collapse of the lungs, spirochetal infection, tuberculosis in childhood, fungus disease, primary carcinoma of the bronchi and lung and electrocardiography, are fully discussed. The illustrations are numerous and carefully worked out to supplement the text. The chief asset of the book is that all phases of diseases of the chest known today are discussed in a practical way. It contains enough detail to make it valuable to the specialist in diseases of the chest and at the same time is so written that the general practitioner, specialists in other phases of medicine, and even the medical student may profit greatly by its study. Therefore it should be brought to the attention of every practitioner of medicine and could well serve as a text and reference book in schools of medicine.

Nasal Accessory Sinuses Roentgenologically Considered By Frederick M. Law M.D. Roentgenologist Manhattan Eye, Ear and Throat Hospital, New York. Volume XX, Annals of Roentgenology. A Series of Monographic Atlases. Edited by James T. Case M.D. Professor of Roentgenology, Northwestern University Medical School, Chicago. Cloth. Price \$10. Pp. 215 with 228 illustrations. New York: Paul B. Hoeber, Inc., 1933.

This volume is printed on good quality paper and is bound like its companion volumes in the Annals of Roentgenology. The work is divided into five chapters, on anatomy, technique and general considerations, roentgenographic technique, interpretation and diagnosis. This division of the subject matter is practical and reasonable. The chapter on anatomy considers the anatomic relations of the sinuses and pays attention to structural variations, which are so important. While the text is clear and concise, this part of the work badly needs a number of drawings illustrating normal anatomic details. Under technique the author discusses general considerations and gives a historical review of the development of the different techniques in use today. The various angles at which the central ray must pass through certain anatomic structures in order to obtain satisfactory results and the position of the patient are considered. Apparatus and instruments are handled separately. This part could be possibly elaborated with benefit. The discussion of the Pfahler sphenoid technic seems rather brief, as does that concerning the Rhese position for disclosing the optic foramen and the Goalwin one for measuring the same structure. Here a number of line drawings would assist materially in aiding the reader to get a mental picture of the features discussed in the text. The third chapter is given over to the consideration of roentgenographic technique, and numerous well done illustrations help to make clear the author's methods and recommendations. The technic as outlined is easy to follow. The position of the patient, tube and film are well portrayed. It is not possible, however, from any of the illustrations to know the exact angle at which the central ray should enter a given anatomic portion

of the skull. In addition to the positions shown, the indications of the angles by dotted lines or otherwise on the original illustrations would allow one to determine these angles at a glance. This chapter is as profuse with illustrations as the previous chapters are lacking. A chapter or subchapter under the head of tubes might possibly have been included, taking up the various types from the gas tube used by Caldwell (whose original article is reproduced practically in toto) to the present type fine focus tubes, especially with the 10 milliamperage focal spot. Special consideration should be given to the use of the line focus tube, which permits of a finer focus being used on account of its special construction, which further permits of a smaller effective focal spot, which latter, while actually larger is smaller in the projected plane in which it is used. The fourth chapter on interpretation, covers the general appearance of pathologic changes in the accessory nasal sinuses and describes a simple method of reporting the observations by means of a clinic card sparing the need of an elaborate detailed report. The final chapter, under diagnosis covers a wide variety of conditions and is profuse in illustrations which are spread over a considerable number of pages. On careful measurement of these illustrations, it appears that it would be possible to put those now occupying two pages on one page, without any sacrifice in quality. This would permit reducing the number of pages to a considerable extent. The illustrations show the pathologic conditions described in an excellent manner and the author is to be complimented on the fine quality of his original work without which it would be impossible to make such fine reproductions. The publication as a whole is well worth while and deserves a place in the library of every radiologist. It is to be hoped however that with the publication of a new edition the author will enlarge on and include descriptions and illustrations of other equipment, such as the Ernst precision apparatus and its modifications as the latter type of equipment bids fair to become the standard apparatus for radiology of the nasal accessory sinuses.

Le cancer du colon droit Par Jean Gosset. Paper. Price 50 francs. Pp. 328 with 73 illustrations. Paris: Masson & Cie, 1933.

During a period of twenty years twenty-six cancers of the right side of the colon were resected by the author's father, Antonin and his collaborators. In France there has been a special tendency on the part of the surgical profession to treat the right half of the colon and the left half of the colon by widely different methods. In Germany, on the contrary little stress is laid on the differences in approach to the treatment of the right and left halves of the colon. Regardless of the site of the growth, the advantages of two methods are discussed "exteriorization" and one stage resection. In America although the rapid method is performed in highly favorable cases, the slow method is employed more as a precaution against local and general complications. The introductory chapter presents the anatomy of the colon in great detail with especial emphasis on the blood supply, which is strikingly demonstrated in the injected specimens. Statistical studies on the relative frequency of cancer in different parts of the colon are contradictory. Males and females are equally affected. The average age in the author's fifty cases was 56 years. Eight per cent occurred in patients under the age of 40 years. The section dealing with gross and microscopic anatomy is well presented and nicely illustrated. In an interesting discussion on the relation between benign polyps and carcinoma, the author quotes various observations. Dukes examined 127 intestines in patients dying of noncancerous diseases and found polyps in 94 per cent of the cases. The association of polyps and cancer is more common. Westhaus, 40 per cent, Dukes 75 per cent, Susman, 45 per cent. The frequency of malignant degeneration of benign polyps is quoted by various authors as between 23 and 50 per cent. The difficulties of estimating the percentage of carcinomas that arise on the basis of benign polyps is pointed out. The recognition of transition stages is difficult, because most lesions are too advanced to permit this study. The symptoms, signs, diagnosis and natural history of the disease are described, as well as the various complications. Of fifty patients operated on by Antonin Gosset, the following procedures were executed: two exploratory laparotomies, two cecostomies, five simple anastomoses between the ileum and

transverse colon, five anastomoses between the ileum and the transverse colon with unilateral exclusion, five simple ileosigmoidostomies, one ileosigmoidostomy with exclusion, ten one stage colectomies with immediate intestinal suture, and thirteen hemicolectomies after preliminary sidetracking. Two were performed with the hope of subsequent resection, which had to be abandoned. Five patients were operated on for acute obstruction. The advantages, disadvantages, indications and contraindications of various surgical procedures are discussed, with elaborate references to various authorities. The monograph, which ends with a series of case reports and an extensive bibliography, is well written and nicely illustrated. It is complete and authoritative in every detail and is welcomed as a valuable addition to the medical literature.

The Foundations of Nutrition By Mary Swartz Rose Ph.D., Professor of Nutrition Teachers College Columbia University. Second edition. Cloth. Price \$3. Pp 630 with 101 illustrations. New York Macmillan Company 1933.

This revised edition summarizes in an interesting manner the knowledge of nutrition. The fundamental subjects of nutrition—energy needs, basal metabolism, proteins, minerals, vitamins, dietetic values of the various classes of foods, the adequate diet, and the food needs of mothers, infants and children—are briefly but adequately handled. The appendix comprises nine practical tables. The author is a recognized authority on this subject. The book is an excellent source of information on the significance of foods to good nutrition and health, it is to be classed among the few leading general textbooks on the subject.

Enuresis or Bed Wetting By R. J. Batty M.D. B.Sc. D.P.H. Assistant Medical Officer to the Lancashire County Council. Cloth. Price 3/6. Pp 91 with illustrations. London John Bale Sons & Danielsson Ltd. 1933.

This small book purports to deal with the causes and cures of bed wetting but does not do so satisfactorily. The conclusions of the investigator, who generalizes from a limited number of cases, cannot always be accepted, particularly when many of the observations recorded are so obvious as not to merit the space given them. For example, the case is reported of a child with enuresis who had to go downstairs and out into the yard to urinate. The doctor recommended the use of a bed chamber, whereupon the bed wetting ceased. This material hardly seems worthy of inclusion in a scientific dissertation on enuresis. The only contribution made by the author is his opinion that threadworms are a frequent cause for bed wetting. Other observations are that bed wetting is a habit which can be corrected by education, any pathologic condition present must be corrected before enuresis can be cured, that mentally deficient children are more likely to be bed wetters than normal children—all observations made previously and of trifling value in solving the problem of enuresis.

Les fous satisfaits Par le Docteur Paul Mondain, médecin chef des asiles publics. Paper. Price 20 francs. Pp 193 with illustrations. Paris Les éditions Vêga 1933.

There is a tendency among French psychiatrists, when writing monographs, to treat of symptoms of mental diseases, in contradistinction to the American practice of having the monograph treat of specific diseases or groups of diseases. The present work is an example of this, in that it is a study of the more pleasing symptoms observed in psychotic cases, such as euphoria, expansiveness and heightened emotional tone. Dr. Mondain classifies happiness grossly into active and passive forms, linking them with various disorders. For two reasons the general tenor of this book is philosophical and interpretative rather than experimental: one is that the physiologic and psychologic factors which lie behind happiness and unhappiness are not yet fully known, the other is that mentally ill patients have as a rule, great difficulty in expressing their thought content, and objective interpretation may be erroneous. The discussions of the happy states—joy, satisfaction and elation—and the interpretations which Dr. Mondain makes, agree in the main with the beliefs of classic psychiatry rather than with those of dynamic psychiatry, and the work of the modern researchers with the Freudian and Adlerian slants has been ignored in favor of quotations from William James. The tech-

nics which he uses to make distinctions between the states of well being exhibited in the various psychoses are the appearance of patients and the patients' reports. Where he uses verbal reports, the author gives few direct productions, except in the last chapter, in which there are a few short case records. The space devoted to each disorder is brief, and it is interesting, in going over the list, to find such archaic entities as megalomania, toxicomania and the deliriums of imagination and reverie. Dr. Mondain's descriptions are clear cut and his style is simple, but it must be admitted that nothing but the author's interpretations and systematizations is new in this book, however, its clear-cut presentation of distinctions between symptoms of "pleasure" makes the book interesting to the psychiatrist. It is illustrated with thirteen full-page pencil drawings, made by the author and showing the expressions of patients suffering from various psychopathologic conditions.

Physiopathologie des syndromes endocriniens Par Noël Flessinger, professeur de pathologie expérimentale et comparée. Paper. Price 40 francs. Pp 317 with 42 illustrations. Paris Masson & Cie 1933.

This is an excellent presentation developed from a course of lectures to students and practitioners, of the fundamentals of physiologic and pathologic endocrinology, including therapy. Unfortunately there is no index and no bibliography, although authorities are freely cited. Pluriglandular syndromes, of which numerous varieties are described or mentioned, are divided into those of early infancy, the period of growth, and adult life. Particular attention is paid to the several forms of gigantism, dwarfism and obesity. A chapter is devoted to the milder forms of hyperfunction, hypofunction and dysfunction of endocrine glands. Several metabolic functions of the kidneys, treated here as endocrinal, would seem more familiar in a different setting. Different functions subserved by the various estrogenic substances are carefully distinguished, although exception may be taken to the author's division of the minor gonadal insufficiencies into physical and psychic types. That one may not yet certainly correlate the two does not seem adequate reason for making this dichotomy.

Medicolegal

Insurance, Accident Septicemia Following Administration of Pollen Extract—The plaintiff was the beneficiary under accident insurance policies, which promised indemnity if her husband died from bodily injuries suffered solely "through external, violent and accidental means." Following an injection of a pollen extract into the husband's arm for hay fever, the complaint alleged, the spores of an anaerobic gas producing organism entered his body, from the effect of which he died. The United States district court gave judgment against the wife in a suit to recover under the policies (1 Fed Supp 951), and she appealed to the United States circuit court of appeals, ninth circuit.

The testimony, said the court of appeals, established a complete and unbroken chain of causation between the injection and the death of the insured—a result that was unforeseen at the time the simple hypodermic treatment was administered. There can be no doubt that the gas-producing organisms entered over the trail blazed by the hypodermic needle. Their entry caused blood poisoning. Blood poisoning caused the death. The evidence discloses, continued the court, no cause of death other than the injection and the resulting infection. In the present advanced state of medical science, such a tragic result from a simple hay fever injection is "unforeseen, unexpected, unusual." It is not necessary to know at what precise instant, by what precise instrumentality, or through what precise avenue the organisms entered the insured's body for it is in the very nature of an accident that its exact causes should not be susceptible of mathematical demonstration.

The insurance carriers contended that, to make the insurance money payable, death must occur as a direct result of a bodily injury effected through external means, that it will not suffice if it appears only that it was accidental in the sense that it

could not reasonably have been anticipated. This contention, said the circuit court of appeals was well disposed of by Judge Sanborn, in *Western Commercial Travelers Assn v Smith* (C C A 8) 85 F 401, 40 L R A 653, in the following language

On the other hand an effect which is not the natural or probable consequence of the means which produced it an effect which does not ordinarily follow and cannot be reasonably anticipated from the use of those means an effect which the actor did not intend to produce and which he cannot be charged with the design of producing under the maxim to which we have adverted is produced by accidental means. It is produced by means which were neither designed nor calculated to cause it. Such an effect is not the result of design cannot be reasonably anticipated, is unexpected and is produced by an unusual combination of fortuitous circumstances.

The same principle was applied in *Mutual Life Insurance Co v Dodge* (C C A 4) 11 F (2d) 486, certiorari denied 271 U S 677, 46 S Ct 629, where the insured's death resulted from paralysis of the respiratory center, caused by the local administration of novocain, preliminary to a tonsillectomy. The death of the insured was held to be caused by accidental means.

The trial court seemed disturbed by the fact that the plaintiff failed to show "just how" the fatal infection occurred. The cogent answer to this objection, said the appellate court is to be found in *International Travelers' Assn v Francis* 119 Texas 1, 23 S W (2d) 282, in which the following language was used:

The cause of death was an infection which produced Ludwig's angina a result so extraordinary and rare and so unrelated to the surgical act performed that it must be regarded as accidental. The drawing of the tooth and treatment following were of course purposeful and not accidental but the infection was not the necessary or usual result of this purposeful act. It was extraordinary unusual and very rare. The proper surgical act therefore must have been accompanied by something unexpected unforeseen and improbable. This unforeseen unexpected and improbable thing was the injection of the pathogenic organisms into the tissues. Just how they were injected the evidence does not show with mathematical precision and in the nature of things this can never be done in any case. These organisms do not make their presence known by ordinary methods of detection.

The circuit court of appeals remanded the case with instruction to enter judgment for the plaintiff—*Jensma v Sun Life Assur Co of Canada*, 64 F (2d) 457.

Compensation of Physicians When Evidence of Patient's Wealth Is Admissible—The plaintiff-physician treated the defendant for uremic poisoning and removed his prostate. He attended him for a period of forty-one days never visiting him less than twice a day and often three or four times a day. He rendered a bill for \$1050. The defendant thought \$500 a sufficient fee and paid that amount and the plaintiff sued for the balance. There was a judgment for the defendant. This was reversed by the St. Louis court of appeals, which ordered a new trial. The court of appeals held that the trial court erred in refusing to permit the jury to consider the defendant's ability to pay the fee charged by the plaintiff, since the defendant himself had offered evidence to show that for services similar to those performed by the plaintiff lower fees were customarily charged. *Glenn v Thompson* (Mo), 45 S W (2d) 948 (J A M A 99 942 [Sept 10] 1932). At the second trial the defendant offered no evidence tending to show a custom of charging a lower fee. The trial court nevertheless instructed the jury that in determining the reasonable value of the services rendered by the plaintiff to the defendant they should take into account the defendant's ability to pay. Judgment was given for the plaintiff, and the patient appealed to the St. Louis (Mo) court of appeals.

The trial court erred, said the court of appeals, in instructing the jury that they should take into account the patient's wealth in determining the physician's fee. When this case was heard on the first appeal, the appellate court held on the record then before it that the defendant himself had raised the issue of a lower standard of charges for similar services and that under such circumstances the trial court erred in refusing to permit the plaintiff-physician to show in rebuttal the defendant's financial condition. At the second trial, however, the defendant presented no such evidence and, said the court of appeals, the rule laid down in *Morrell v Lawrence*, 203 Mo 363, 101 S W 571, applied. In that case the Supreme Court of Missouri held that only when the defendant introduces evidence to show that the plaintiff charges smaller fees for similar services to certain

patients is the plaintiff entitled to show by rebuttal evidence that the smaller fees are charged to poor men because of their poverty. The plaintiff then may show that such smaller fees are not the customary and usual charge made to those who are able to pay the reasonable value of the services, and in that connection he may show the patient's financial standing to prove that it "does not entitle him to such indulgence." To that extent only, and for rebuttal purposes only, is such evidence proper. Regardless of what the rule may be in some other state as to the admissibility of evidence and the propriety of instructions, relating to a patient's financial ability to pay for services rendered by a physician, the Supreme Court of Missouri has definitely held that in Missouri the jury in such a case "have no concern with the question of the defendant's ability to satisfy the judgment." The judgment of the trial court was reversed and the cause remanded for another trial—*Glen v Thompson* (Mo), 61 S W (2d) 210.

Evidence Lay Testimony as to Physical Condition, "Total Disability" Defined—A layman, says the Court of Appeals of Kentucky, may testify as to the outward physical condition of and the effect of an ailment on, a person whom he has had ample opportunity to observe. A layman, however, although he associated with the one about whom the testimony is to be given may not express an opinion concerning the existence of facts not open to his observation and which are obtainable only through scientific and expert knowledge. "Total disability" within the meaning of insurance policies does not mean absolute helplessness or complete physical disability. A disability is total and complete when the insured is unable to do and perform in a reasonable and practical way all material acts in the pursuit of his occupation or employment or, perhaps in some cases, any other occupation for gain—*Aetna Life Ins Co v Wiant* (Ky), 61 S W (2d) 50.

Malpractice Necessity for Expert Testimony—What does or does not constitute proper medical practice or the usual practice in treatment may be established only by expert testimony. If the question is one solely within the knowledge of experts their testimony is conclusive. If however, the question is one that may be ascertained by a lay witness expert testimony is not necessary, and a court is not bound by expert testimony with respect to such a question—*National Automobile Ins Co v Industrial Accident Commission of Calif* (Calif), 22 P (2d) 568.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers to THE JOURNAL in continental United States and Canada for a period of three days. Periodicals are available from 1925 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Persistence of Tuberculous Infections — Robertson reviewed the entire series of necropsies performed at the Mayo Clinic over a period of six years (1926-1931 inclusive) in order to determine the relative incidence of the various classes of tuberculous processes. During these six years approximately 3,306 postmortem examinations revealed an incidence of some form of tuberculous lesion in 2,064 (62.43 per cent). Of this group, in eighty-nine cases tuberculosis was either a principal or the contributing cause of death, and in 1,725 cases the tissues examined contained apparently entirely healed tuberculous processes. On the basis of his observations and studies reported by other investigators the author concludes that 1 Tuberculous infections may occur and pursue their entire course without demonstrable clinical phenomena, that is, without attracting the attention of the patient or the physician to their presence. 2 Recognized tuberculous infections may subside and be regarded throughout remaining life as healed and still remain continuously active. 3 Apparently healed tuberculous lesions may become clinically active after varying intervals. 4 No form of physical examination can give assurance that any person does not harbor the menace of active tuberculous infection. 5 The safest rule for physicians and patients alike is to regard tuberculosis as possessing an ever present potentiality for becoming active. One can almost say "Once infected always infected."

Diagnosis of Tumors by Aspiration — Needle aspiration in the experience of Stewart is an expeditious practical method

for the diagnosis of tumors. In approximately 2,500 cases he has observed no untoward result following its use. The interpretation of smears of aspirated material often requires competent clinical assistance. Diagnosis by aspiration is as reliable as the combined intelligence of the clinician and pathologist makes it. The pathologist who ventures to interpret the material obtained by aspiration will have to revise or relearn many criteria. The clinician must appreciate how far the pathologist can logically go in interpreting the smear. Both must maintain a sympathetic attitude toward a new procedure. It is safe to state that in the author's institution the method has so established its usefulness that it has acquired a permanent place as a means of diagnosis.

Action of Morphine on Small Intestine — Orr observed that morphine and related opium derivatives, when given hypodermically, stimulate the tone, the rhythmic contraction and, in some degree, the peristaltic waves of the small intestine for a period of at least six hours. To prevent overdistention of the small intestine, morphine is indicated in the treatment of acute peritonitis, intestinal obstruction and so-called paralytic ileus. The maximal clinical benefits can be obtained only by giving morphine in sufficient dosage to produce continuous narcosis. By maintaining the tone and rhythmic contractions of the small intestine with morphine, distention is controlled and disturbance of the intestinal circulation is prevented during the course of the disease until the cause of the intestinal distention is overcome by the natural defensive powers of the patient.

Vestigial Mastitis — From a study of six cases of vestigial mastitis, Moschcowitz arrives at the following conclusions: 1 There exists in certain persons an abnormal persistence of the milkridge in some part of its normal course. 2 Such a persisting milkridge is absolutely symptomless and is therefore not discoverable. 3 For some reason or other, this abnormally persisting line may become changed pathologically (the author presumes inflamed, judging from the one section that he has been able to study) and it then gives rise to the various symptoms and physical signs in consequence of which it becomes discoverable. 4 Finally, one must also arrive at the conclusion that if the lesion were discoverable or had actually been discovered, it has not been heretofore recognized. In the main, the principal complaint of these patients is pain or functional disability, or both, either below the breast extending for a variable distance on the abdomen, or above the breast extending toward the corresponding shoulder and axilla. The preeminent

physical observation is the presence of a cordlike structure in certain characteristic locations and only in these—namely, either on the abdomen or on the thorax and axilla or both. The cords are found only in the course of a narrowly circumscribed line, which begins in the lateral part of the axilla and runs toward the chest, on reaching the chest, the line curves downward to reach the upper border of the breast in the nipple line. The inframammary portion of the line begins at the inferior border of the breast in the nipple line and runs, slightly converging toward its fellow on the opposite side in the general direction of the symphysis pubis. The cords vary in length. The cord imparts the same sensation to the examining finger as an adult vas deferens. The lesion exists in both sexes.

Rupture of Liver Without Tear of Capsule—Robertson and Graham report two cases of subcapsular rupture of the liver with operation and recovery. In one case the seriousness of the injury was recognized early, the tumor appeared early and at operation the cavity was found to be filled only with blood. In the other case there was a long latent period of well being between the accident and the appearance of the tumor which at operation contained bile and blood and was accompanied by gross destruction of the tissue of the liver. If a patient suffers an abdominal injury with distress referred to the right side and accompanied by pain in the shoulder, early exploration is advisable, as there will be a shorter convalescence and it will avoid destruction of the tissue of the liver should the diagnosis prove to be a subcapsular rupture of the liver. If the tumor occurs soon after the injury the authors presume that its contents will be blood, and drainage with a tube appears to be the ideal method of handling it. If it is late in forming bile will constitute an important volume of the content of the cavity, and marsupialization is desirable.

Determination of Activity in Rheumatic Infection—Struthers and Bacal state that congenital heart disease shows no worthy alteration of the white blood cell count, the sedi-

mentation rate, the sleeping pulse and the weight of the body. Uncomplicated acute rheumatic fever shows a high sedimentation rate, usually a leukocytosis of from 12,000 to 15,000, fever, approximation of the sleeping and waking pulses during the period of fever, and loss of weight. All these evidences of activity tend to subside together with the clinical evidence of subsidence of the infection. Chorea without carditis shows no alteration in the total white blood cell count, sedimentation rate or fever, there is usually a marked difference between the sleeping and waking pulses, the former being normal. Under treatment there is usually a gain in weight. Rheumatic fever with carditis shows marked alteration of the sleeping pulse, the white blood cell count and the weight of the body, which tend to return to normal with the subsidence of the infection. The sedimentation rate, however, requires a period of months to return to normal and hence is probably the most delicate of these tests in the determination of activity of rheumatic infection, excepting in the presence of cardiac failure with edema, when it falls rapidly to levels below the normal and is of grave prognostic import. Chorea complicated by carditis, even in the absence of fever, shows the same changes in these criteria as does rheumatic fever with carditis, excepting the absence of leukocytosis.

Active Pulmonary Tuberculosis and Diabetes—Kennedy found only forty-one cases of active pulmonary tuberculosis among 2,500 patients who had active diabetes—an incidence of 1.6 per cent. The youngest patient was 20 years of age, and the average age for the group was 44.8 years. None of the juvenile diabetic patients have as yet had tuberculosis. Tuberculosis in diabetes may be acute, chronic or of a latent type detectable only by roentgenography, and the lesion may be of the nondiabetic adult apical type or of the hilus pneumonic variety. In either case it is usually a fresh process, and the hilus pneumonic type of lesion may be so situated that the ordinary clinical methods of examination may fail to detect it. This emphasizes the importance of periodic roentgen examination. The observation of increased root shadows in the diabetic patient should always be regarded as tuberculosis until proved otherwise. The apical type of lesion was less fatal than the hilus pneumonic type, but, regardless of the lesion, mortality was definitely related to the degree of control of the diabetes. Uncontrolled diabetes is an unfavorable prognostic sign. A sugar-free urine and normal blood sugar should be the aim in treatment. Treatment of diabetes with tuberculosis is identical with that of diabetes without tuberculosis, so far as diet and insulin are concerned. Overfeeding may be attempted, but it should be continued only when the excess food can be so counterbalanced by insulin that the urine is free of sugar and the blood sugar is normal. Otherwise it is best to keep the caloric value of the diet at a normal level.

Treatment of Trigeminal Neuralgia—McKenzie points out that partial section, by the temporal route, is a much more satisfactory procedure than complete section in trigeminal neuralgia. This includes the fairly common type of patient in whom the pain commences in the second and third divisions and spreads up through the eye and forehead. In these patients the main trigger spots are in the second and third division and partial section is usually indicated, even though a subsequent operation may occasionally be necessary. Complete section is condemned because of the number of severe eye complications. It is definitely indicated only in the comparatively few patients in whom the pain commences in the first division. Partial section by the temporal route is such a satisfactory, safe and simple procedure that the cerebellar approach advocated by Dandy has been adopted only occasionally. It is especially indicated when it is considered necessary to cut both the glossopharyngeal and the trigeminal nerves and in patients in whom the presence of a small angle tumor is suspected. In two patients, on whom partial section was performed after the manner described by Dandy, the sensory loss was identical with that usually found after partial section by the temporal route, these observations are at variance with the views of Dandy and Davis, the latter feeling that a partial section as described should cause the greatest sensory loss in the first division area, whereas Dandy states that there is no sensory loss.

Glycerin Extract of Suprarenal Cortex Potent by Mouth—Freeman and his associates treated nine schizophrenic patients during three periods, each with glycerin extract of suprarenal cortex. The dosage varied at different times from a fresh gland equivalent of 30 grains (2 Gm) to 450 grains (30 Gm) daily. The medication periods were thirteen, nine and five weeks, respectively. The systolic blood pressure was increased, on an average, 34, 24 and 22 mm of mercury, respectively, during the three medication periods. There was a slight residual pressor effect maintained during the intervals between medication periods. The diastolic pressure was increased 20, 11 and 20 mm of mercury, respectively, in each period. The cardiovascular reactivity of the patients to environmental excitement, to change of posture and to exercise was increased during the medication period. The effect became progressively greater from 7 a m to 9 p m. The body weight was slightly though significantly increased, as was the specific gravity of the urine. The pulse rate and the blood cholesterol level seemed to have been significantly lowered. Changes in several other functions were suggestive, but the data were not sufficiently numerous to permit accurate judgment. The evidence secured is to the effect that neither maximal effective dosage nor duration was employed. The authors conclude that glycerin extract of suprarenal cortex is a potent medicament for the elevation of blood pressure and for increasing cardiovascular reactivity.

Sugar Tolerance in a Case of Addison's Disease—Turner reports a case of Addison's disease in which there was a marked increase in carbohydrate tolerance. The initial sugar tolerance curves were inverted. The reaction to a combined epinephrine sugar injection suggested that the increased tolerance was associated with a relative hyperinsulinism resulting from degenerative processes interfering with the normal production of epinephrine. Clinical evidence indicated medullary as well as cortical involvement of the suprarenals. Although reports of blood sugar studies in Addison's disease are numerous the author has been unable to find any instances in which there has been an actual inversion of the sugar tolerance curve. He presents his case because of the unusual blood sugar reactions obtained in which there apparently was a sufficient preponderance of insulin activity actually to invert the sugar tolerance curves.

Possible Cause of Uterine Fibroids—Witherspoon offers a series of 275 cases of fibroids the analysis of which evidences a possible etiologic relationship between continuous estrin stimulation from the ovary and the formation of hyperplasia of the endometrium and of fibromyomatous growths of the myometrium. His assumption is that the unopposed action of estrin on the uterus results first in immediate endometrial changes characterized by hyperplasia and then in more latent myometrial disease in the nature of fibromyomatous growths. With this hypothesis as a basis twenty-six operative cases of hyperplasia of the endometrium diagnosed as such and in which a second operation for multiple fibroids was performed after an approximate interval of four years and four months

are analyzed. In addition, 124 cases of fibromyomas in white women and 125 in Negro women, diagnosed microscopically, are offered with the associated ovarian and endometrial observations, as presenting added evidence in support of a cause and effect relationship between hyperestrin stimulation, hyperplasia of the endometrium and fibromyomatous growths of the myometrium. The principal symptoms between the first and second operations were an increase of complaints. Both bleeding and pain increased after the first operation, while an abdominal mass appeared in five instances. In every case the microscopic diagnosis of the curettements from the first operation was hyperplasia of the endometrium. At the second operation, multiple fibroids were observed (100 per cent) even though no such tumors were noted clinically at the time of the first operation, which involved abdominal exploration in thirteen, or 50 per cent, of the cases. In addition to the fibroid growths, the endometrium was hyperplastic in twenty-four, or 92.3 per cent, of the cases, in two instances in which hyperplasia of the endometrium was not noted, a developing yellow body was found in one of the ovaries. Follicle cysts of the ovaries were present in all twenty-six cases, including those in which the yellow bodies were found. Salpingitis, or adhesions from previous operations, or endometrial transplants, were found in twenty-five. This tube ovarian infection is offered as a possible etiologic factor in follicle cyst formation, either through an inherent ovarian defect or because of a thickening of the ovarian capsule. In the 124 white patients having fibroids, follicle cysts were found in every instance, while no mature yellow body was noticed. Hyperplasia of the endometrium was diagnosed microscopically in every case. In the 125 cases of Negro women having fibroids, ovarian follicle cysts were observed in 96.8 per cent. The microscopic study of the endometrium was not available in a sufficient number of cases to justify its inclusion. A 100 per cent incidence of salpingitis associated with fibroids was present in the Negro women.

Electrosurgical Removal of Gallbladder—Thorek describes a method of electrosurgical removal of the gallbladder that may be used without resort to drainage. Nitrous

oxide and oxygen or ether are used for general anesthesia. The abdomen is opened with a scalpel or a diathermy knife. The field of operation is isolated with moist warm laparotomy sponges, the contents of the gallbladder are aspirated, the cystic duct is ligated between two catgut ligatures and divided, the gallbladder is incised from above downward, and the stones are removed. The redundant portion of the gallbladder is removed and the remaining part is electrocoagulated thoroughly. The field to be coagulated must be dry. The peritoneal edges are approximated over the coagulated area. A fine curved needle to which a number 0 catgut is swaged is used. To guard further against the possibility of biliary seepage from the cystic duct and to supply serous surfaces the falciform ligament may be mobilized and swung over onto the site of the bed of the liver and attached with a few sutures of fine catgut. Careful hemostasis and exact closure of the abdominal wound complete the operation.

Treatment of Acute Gonorrheal Epididymitis by Injection of Whole Blood—Berlin injected 1 cc of the patient's whole blood into the epididymis in sixty-two cases of acute gonorrheal epididymitis. All patients were ambulatory, receiving no other treatment besides the autohemotherapy, except some scrotal support by suspensory bandages and hot applications (when available). Local treatment for gonorrhea was resumed after the symptoms of acute epididymitis had subsided, when residual infection in the urethra or its accessory glands was present. Marked improvement to a total subsidence of pain and tenderness had usually occurred within two to twelve hours after the first injection. As a rule at the subsequent injections the testicles and epididymis could be handled without much discomfort or pain to the patient. Some resorption of inflammation and reduction of swelling was usually observed after the second injection. After the third injection the epididymis was normal on palpation in eighteen cases, after the fourth in thirty-two, after the fifth in forty, after the sixth in forty-three, and after the eighth in forty-five. In six cases resolution did not take place completely and there remained a small amount of swelling after eight injections were given. The maximal improvement was noted after the third injection. A scrotal abscess occurred in a Negro patient; this was incised and drained and it healed promptly. There were six recurrences of epididymitis, which were due to the discontinuance of treatment on the part of the patients of the infection of the posterior urethra, prostate or vesicles, which was still present. Contraindications of this treatment are (1) extreme nervousness and hypersusceptibility to pain on the part of some patients, (2) marked elevation of temperature, chills and so on at the time of treatment, (3) a severe or fulminating type of epididymitis and (4) the presence of gross suppuration of the epididymis, i. e. conditions in which surgical intervention is indicated. The blood (1 cc) is injected rapidly into the center of the involved area, the scrotal skin is disinfected previously with alcohol or mercurochrome. It is preferable to use a 5 cc Luer-Lock syringe with a fine needle, about 23 or 24 gage and 1¼ inches long. The injections are made at a depth of from 1 to 3 cm, depending on the degree of edema and infiltration of the surrounding tissues, and are repeated at intervals of twenty-four or forty-eight hours, depending on the tension of the inflamed tissues. If it requires from fifteen to twenty minutes or longer for the tension to subside, the next injection is not made until after forty-eight hours. If the tension yields in from two to five minutes, the injection is repeated on the following day. The first injection should be given as soon as possible after the onset of the epididymitis. The sooner the injection is given, the more rapid is the cure.

Idiopathic Dilatation of Common Bile Duct in Children—Gross reviews fifty-two cases of idiopathic choledochal cyst in childhood and reports two of his own. The more important symptoms and signs are usually characteristic and consist of abdominal pain, abdominal tumor and jaundice. The size and tenseness of the abdominal tumor in a given case may vary from time to time. Acholic stools may be present and there may be bile in the urine. The average duration of symptoms was about three years. In approximately half of the cases the symptoms had been intermittent and had occurred in attacks with intervening periods of remission. About three-fourths of the patients were females. The correct diagnosis was made only three times before operation, but the nature of the history and the physical observations should enable the diagnosis to be made more frequently. The important pathologic observation is a large cystic dilatation of the common duct. In half of the cases there was an angulation, stenosis, obliteration or valve formation at the cyst outlet, but many of these conditions were probably the result rather than the cause of the enlargement of the common duct. The liver was practically always enlarged, and biliary cirrhosis and cholangitis were common. The etiology of the condition has not been definitely determined, but many theories have been advanced. The dilatation of the common duct is most likely a result of congenital weakness of the wall of the duct, which is not productive of enlargement until there is obstruction to the flow of bile. Such an obstruction may be from congenital stenosis, valve formation, angulation or cholangitis of the lower part of the common duct. The accepted form of treatment is to anastomose

the biliary and the intestinal tracts at one operation, the most acceptable method of doing this being the production of a choledochoduodenostomy. The mortality in the entire group of fifty-two patients was 69 per cent, but in those treated by primary anastomosis of the biliary tract and the intestine the mortality was 9 per cent.

Rhabdomyoma of the Larynx—Imperatori reports a case of rhabdomyoma of the larynx in a man, aged 23. Ten months previous to the first examination, he gradually became hoarse. Physical examination was negative except for a lobular sessile growth attached to the posterior third of the left cord on its superior surface. There was no appearance of infiltration. The growth was about the size of two green peas and was light red. There was considerable air wasting on phonation and the voice was hoarse. The right cord appeared to be normal. Under local anesthesia and with the use of a Jackson laryngostat the growth was removed with a cup type of forceps and the remaining tags with a biting forceps. Microscopic examination of the excised tissue disclosed a covering of stratified squamous epithelium that showed irregular thickening with irregular prolongations at the base. At one point the epithelium showed transition to the columnar type. Several ducts of mucous glands showed metaplasia of the epithelial lining from columnar to squamous in type. The stroma beneath the epithelium was formed chiefly of spindle cells, which seemed to represent muscle fibers. With special staining these spindle cells were further identified as striated muscle fibers. They varied in size and shape. Some of them were embryonal in type some of them were multinucleated and still others showed communicating branches with central nuclei as in heart muscle. Mitotic figures were not found. Intermingled with the muscle fibers there was a small amount of fibrous tissue especially beneath the epithelium. There was no recurrence of the growth four months later, and the patient's voice was of normal volume and quality.

Vitamin D Milk in Treatment of Infantile Rickets—Kramer and Gittleman treated ten children suffering from rickets with vitamin D milk produced either by irradiating the milk directly with the carbon arc lamp or by feeding irradiated yeast to the lactating cattle. The ten infants were divided into four groups, making it possible to feed each of the milks at two levels of vitamin D, that is, 55 and 40 Steenbock units respectively per child daily. In each group healing began in from seven to thirty-one days, the average period being about two weeks. Healing was well advanced in from four to six weeks. The calcium and inorganic phosphorus concentrations of the serum followed the same course as during treatment with cod liver oil. Infants showing a low calcium or a low phosphorus or a decrease in the level of both elements in the serum responded equally well to the two types of vitamin D milk when these were fed at either a high or a low level. Aside from gastro-intestinal disturbances resulting from accidental infection, the milk was well tolerated by all the children. The authors believe that the controls used were sufficient to exclude the possibility of spontaneous healing due to chance irradiation or to foods inadvertently endowed with antirachitic properties. Because of seasonal effect, it would be desirable to repeat these observations during a season of the year when rickets is most likely to be active and when spontaneous healing is least likely to occur.

Foreign Body in the Bladder Report of Case A W Muthaif El Paso Texas —p 384

Therapeutic Use of Bacteriophage—Dutton used filtrates that contained not only bacteriophage but also growth products and a high concentration of a bacterial protein. For this reason he prefers to use the term "filtrates of bacteriophage lysed cultures" instead of only bacteriophage. The bacteriophage used must be highly potent to secure any results. A great many of the failures reported in the literature were undoubtedly due to the use of a weak bacteriophage. In the case of staphylococcal infections, both local and systemic, the bacteriophage has proved to be of inestimable value. In many other infections the results have been so encouraging that it is well worth the effort to secure the remarkable benefit possible, even in a limited number of cases. The author reports ten cases of staphylococcal septicemia in which 2 cc of staphylococcus bacteriophage was given of which five were extremely severe and presented a grave prognosis, four resulted in recovery. In the remaining five cases recovery was complete, although they were not severe and probably would not have been diagnosed as septicemia except under the stimulus of almost routine blood cultures in febrile cases and it cannot be said that they should

fall in the same category as those cases in which a fatal termination is expected. Systemic reactions seldom follow the subcutaneous or intravenous injections of staphylococcus bacteriophage, nor does any considerable local reaction develop. No evidence of anaphylaxis has ever been observed with intravenous or subcutaneous injections. All the bacteriophage used was prepared in the usual manner originally described by d'Herelle. All filtrates were adequately controlled for sterility. The stock bacteriophage used was incubated for at least two weeks. Autogenous bacteriophages were not considered practicable, owing to the length of time necessary to prepare and control them. The author insists on doses not over 2 cc subcutaneously and 1 cc intravenously. In his experience no reactions attributable to peptone have ever occurred.

Chronic Mastitis.—Taylor states that chronic mastitis of the type characterized by pain, ill defined nodules and diffuse swelling has a marked tendency to spontaneous improvement. Following the physiologic changes of pregnancy or the menopause, improvement may be especially marked. The elimination of pelvic lesions by either surgical or nonsurgical treatment is followed by a somewhat greater proportion of cures than is observation alone. When important pelvic lesions exist, their correction should be the first step in the treatment of diffuse mastitis. Irradiation of the ovaries either with the production of an artificial menopause or by a smaller dose is effective although applicable only to certain cases. The administration by mouth of the older forms of ovarian extract or residue is useless. The trial of a more potent modern preparation of follicular and anterior pituitary hormones is indicated in the cases in which breast symptoms are associated with disturbed menstruation.

Chronic Cicatrizing Enteritis, Regional Ileitis (Crohn).—Harris and his associates point out that Crohn, Oppenheimer and Ginzburg have described a surgical disease which they call 'regional ileitis'. This disease has well defined clinical and pathologic characteristics and its description will be found to cover many of the heretofore unclassified inflammatory tumors and lesions of the small intestine. The authors report three cases of the disease in one of which the jejunum was found to be involved. They suggest the name 'chronic cicatrizing enteritis' as a more descriptive and inclusive term for this new surgical entity. Medical treatment is symptomatic

and supportive. A complete cure must depend on the surgical resection of the diseased intestine. In cases in which this has been done successfully, the patient has been restored to complete health. Such a case may require multiple stage operations. In the authors' experience a preliminary short circuiting operation such as ileocolostomy, with a later resection of the diseased intestine when the patient has been built up would seem to be the better surgical judgment. Simple ileocolostomy without the removal, either at the original operation or later of the diseased obstructed intestine carries with it the added danger of the obstructed intestine becoming dilated and ulcerated. The recent work of Holm has definitely shown both experimentally and clinically that the sidetracked intestine in short circuiting operations is a constant menace to the health of the patient. Berg advocates resection with ileocolostomy as the operation of choice.

Varicography.—Pomeranz and Tunick observed that the injection of skiodon into varicose veins offers a safe method of visualizing roentgenologically the venous system. By the use of this chemical during fluoroscopy they were enabled to observe the circulation of the blood in diseased veins and its variations during changing mechanical conditions. The statistical implications of the Trendelenburg test observed by this method by McPheters have been confirmed by the authors. By the use of stereoscopic plates the physical conditions of the vein at the time of injection can be recorded. The use of the chemical results in sclerosis of the affected vein which is painless and unaccompanied by phlebitis. The authors have demonstrated the presence of venous pools and feeder veins in the vicinity of varicose ulcers. They state that any syringe and needle used in the injection treatment of varicose veins may be employed and from 5 to 20 cc of a 40 per cent solution of skiodon is sufficient. The patient is prepared as for intravenous medication. The use of the tourniquet is optional as venous dilatation is so great that satisfactory plates may be taken without its use. To test the mechanics of the Trendelenburg test the tourniquet must be employed. The patient is placed on or in front of the fluoroscope and the needle inserted into the vein. When the needle is within the vessel, the material is injected slowly and without undue pressure during fluoroscopy and the veins are studied under varying conditions of pressure and posture. For record purposes, stereoscopic plates are taken. The limb is placed on a plate changing device and the vein injected while the plates are being taken. The needle should not be removed between exposures, since it serves as a guide to the site of injection and prevents back flow of the skiodon on the skin as its superimposed density often masks finer vascular changes.

Sodium Morrhuate Therapy in Varicose Veins.—Biegeleisen presents an evaluation of the merits of sodium morrhuate therapy in varicose veins based on a detailed study of 561 injections. He studied four preparations. Their composition was as follows: Product A was a 5 per cent solution of sodium morrhuate with 0.5 per cent phenol, product B was a 5 per cent solution of sodium morrhuate with 5 per cent benzyl alcohol added, product C was a 5 per cent solution of sodium morrhuate without any adulterant, and product D was also a 5 per cent solution of sodium morrhuate with 0.5 per cent phenol. Product A was made by an American firm that imported powdered sodium morrhuate from England and subsequently dissolved it in water with the addition of 0.5 per cent phenol. Products B and C represented American preparations manufactured in one operation at the same plant, and product D was made in England and the finished product distributed in America. The technic employed was uniform throughout. The injections were made with the patient in the standing position. No tourniquets were used. The majority of injections were in 2 cc quantities. Product A was used in ninety-six injections. Only 43 per cent of the injections made were efficient from a clinical standpoint. These poor results were particularly significant since the ampules secured were fresh and used almost immediately. Product B was studied in two parts because two different batches of sodium morrhuate from the same source were tested against each other. The first batch consisted of a shipment of ampules that were used for 180 injections. The second batch was used in seventy-five injections. The first

shipment of ampules produced thirty very good results fifteen of these reactions were attributed to high dosage, 5 cc., and the fifteen others could not be accounted for by massive dosage, since no more than 2 cc. was used. Of the treatments, 18 per cent were failures. Altogether, 81 per cent of the injections in this group gave definite thromboses and did not need repetition. There were no severe reactions produced from the second shipment of ampules of product B. 56 per cent were clinical successes and 44 per cent failures. It is evident that there is a definite variability as to the potency of the different shipments from the same source. With product C, 150 injections were made and it was noted that there was no difference between this preparation and the one with benzyl alcohol. Successful results were obtained in 62 per cent. No loss of efficiency was evident when local anesthetics were excluded from the mixture. Product D did not differ from the similar American preparation. On the basis of these observations the author concludes that 1 Sodium morrhuate is an unknown, relatively unstable mixture of sodium salts of the unsaturated fatty acids found in cod liver oil. 2 Its potency diminishes with age and is not uniform. 3 It is occasionally capable of slough formation. 4 No local anesthetic should be added to the mixture. 5 The advisability of incorporating an antiseptic in the solution is open to question. 6 The irritating effect of sodium morrhuate is due to its soapy characteristics and has been duplicated experimentally by a solution of commercial liquid soap. 7 Sodium oleate, which is one of the fatty acid salts present in sodium morrhuate, has been tested and found to possess sclerotic power. 8 The continued testing of the other fatty acid salts present in the mixture is necessary if a standardized pure product is to be developed.

Effect of Fungus Spores in Maple Bark on the Lungs
—Towey observed that maple logs that have been cut for a period exceeding one year show evidence of fungus infection. In the affected maple logs a black dust of the consistency of lampblack is found beneath the cork layer of the bark, and this dust on examination has proved to be the pure spores of fungi (*Coniosporium corticale*). A number of men whose working operations brought them into contact with this spore dust have developed definite asthmatic attacks. A clinical, roentgen and laboratory examination has been made on a group of thirty-five patients. The symptoms presented were acute and typically asthmatic in character. The predominating symptom was shortness of breath, associated with loss of weight, cough varying amounts of expectoration, substernal pain and temperatures ranging to 103 F in certain instances. Physical signs were those commonly associated with acute asthmatic attacks with coarse rales predominating over the lower half of the chest. Roentgenograms show definite mottling throughout the lower half of the lungs in the most severe cases with a definite increase in the basal trunk and peribronchial shadows. The symptoms began to improve as soon as the patient was removed from the environment and the roentgenograms showed a relatively rapid clearing. The abrupt onset with the fairly prompt recovery from symptoms on removal of the patients from the environment suggested the problem of a protein sensitization. Reactions to intradermal injections of the spore extract and a suspension of spore dust as compared to controls were indefinite and more work is being done to establish the mechanism of the disease.

Artificial Menopause—Martindale presents the end results, nature and duration of the artificial menopause, the way in which it differs from the normal menopause, the best and safest ways to induce an artificial menopause and the indications and contraindications for the various methods based on a study of 620 cases. Her conclusions are that 1 Each method of induction has its definite function. Surgical operation is the correct method for all cases in which a malignant condition or degeneration of a nonmalignant fibroid is suspected, for all young patients in whom myomectomy may be possible and for those in whom the fibroid uterus is of a certain size and causes pressure symptoms. Irradiation is the treatment of choice in all cases of climacteric hemorrhage, with fibrosis of the uterus or small interstitial fibroids, in which there is no suspicion of carcinomatous or sarcomatous degeneration. 2 The menopausal symptoms in irradiated patients are no more severe than, in fact, not as severe as, in those of the normal climacteric. 3 The temporary amenorrhea caused by irradiation is a valuable method of treatment in certain cases of psychosis and tuberculosis. 4 The risk of malignant disease occurring in an irradiated uterus is no greater than, if as great as, the risk of carcinoma occurring in it or in any other organ of the body in an untreated case. 5 Accuracy in diagnosis is one of the essential factors in successful treatment. To ensure success the patient must remain under the care and supervision of the gynecologist, who, if he does not himself undertake the radiologic part of the treatment, will at any rate work in close cooperation with the radiologist—an easier ideal to attain now that so many gynecologic departments have their own intensive x-ray plant and an adequate supply of radium.
